

NONLINEAR AGGREGATION-DIFFUSION EQUATIONS: RADIAL SYMMETRY AND LONG TIME ASYMPTOTICS

J. A. CARRILLO¹, S. HITTMEIR², B. VOLZONE³, Y. YAO⁴

ABSTRACT. We analyze under which conditions equilibration between two competing effects, repulsion modeled by nonlinear diffusion and attraction modeled by nonlocal interaction, occurs. This balance leads to continuous compactly supported radially decreasing equilibrium configurations for all masses. All stationary states with suitable regularity are shown to be radially symmetric by means of continuous Steiner symmetrization techniques. Calculus of variations tools allow us to show the existence of global minimizers among these equilibria. Finally, in the particular case of Newtonian interaction in two dimensions they lead to uniqueness of equilibria for any given mass up to translation and to the convergence of solutions of the associated nonlinear aggregation-diffusion equations towards this unique equilibrium profile up to translations as $t \rightarrow \infty$.

1. INTRODUCTION

The evolution of interacting particles and their equilibrium configurations has attracted the attention of many applied mathematicians and mathematical analysts for years. Continuum description of interacting particle systems usually leads to analyze the behavior of a mass density $\rho(t, x)$ of individuals at certain location $x \in \mathbb{R}^d$ and time $t \geq 0$. Most of the derived models result in aggregation-diffusion nonlinear partial differential equations through different asymptotic or mean-field limits [59, 12, 23]. The different effects reflect that equilibria are obtained by competing behaviors: the repulsion between individuals/particles is modeled through nonlinear diffusion terms while their attraction is integrated via nonlocal forces. This attractive nonlocal interaction takes into account that the presence of particles/individuals at a certain location $y \in \mathbb{R}^d$ produces a force at particles/individuals located at $x \in \mathbb{R}^d$ proportional to $-\nabla W(x - y)$ where the given interaction potential $W : \mathbb{R}^d \rightarrow \mathbb{R}$ is assumed to be radially symmetric and increasing consistent with attractive forces. The evolution of the mass density of particles/individuals is given by the nonlinear aggregation-diffusion equation of the form:

$$\partial_t \rho = \Delta \rho^m + \nabla \cdot (\rho \nabla (W * \rho)) \quad x \in \mathbb{R}^d, t \geq 0 \quad (1.1)$$

with initial data $\rho_0 \in L^1_+(\mathbb{R}^d) \cap L^m(\mathbb{R}^d)$. We will work with degenerate diffusions, $m > 1$, that appear naturally in modelling repulsion with very concentrated repelling nonlocal forces [59, 12]. These models are ubiquitous in mathematical biology where they have been used as macroscopic descriptions for collective behavior or swarming of animal species, see [53, 13, 54, 55, 67, 16] for instance, or more classically in chemotaxis-type models, see [60, 44, 40, 39, 11, 10, 20] and the references therein.

On the other hand, this family of PDEs is a particular example of nonlinear gradient flows in the sense of optimal transport between mass densities, see [2, 26, 27]. The main implication for us is that there is a natural Lyapunov functional for the evolution of (1.1) defined on the set of centered mass densities $\rho \in L^1_+(\mathbb{R}^d) \cap L^m(\mathbb{R}^d)$ given by

$$\begin{aligned} \mathcal{E}[\rho] &= \frac{1}{m-1} \int_{\mathbb{R}^d} \rho^m(x) dx + \frac{1}{2} \int_{\mathbb{R}^d \times \mathbb{R}^d} \rho(x) W(x-y) \rho(y) dx dy \\ \rho(x) &\geq 0, \quad \int_{\mathbb{R}^d} \rho(x) dx = M \geq 0, \quad \int_{\mathbb{R}^d} x \rho(x) dx = 0, \end{aligned} \quad (1.2)$$

being the last integral defined in the improper sense. Therefore, if the balance between repulsion and attraction occurs, these two effects should determine stationary states for (1.1) including the stable solutions possibly given by local (global) minimizers of the free energy functional (1.2).

Many properties and results have been obtained in the particular case of Newtonian attractive potential due to its applications in mathematical modeling of chemotaxis [60, 44] and gravitational collapse models [61]. In the classical 2D Keller-Segel model with linear diffusion, it is known that equilibria can only happen in the critical mass case [9] while self-similar solutions are the long time asymptotics for subcritical mass cases [11, 18]. For supercritical masses, all solutions blow up in finite time [40]. It was shown in [48, 19] that degenerate diffusion with $m > 1$ is able to regularize the 2D classical Keller-Segel problem, where solutions exist globally in time regardless of its mass, and each solution remain uniformly bounded in time. For the Newtonian attraction interaction in dimension $d \geq 3$, the authors in [8] show that the value of the degeneracy of the diffusion that allows the mass to be the critical quantity for dichotomy between global existence and finite time blow-up is given by $m = 2 - 2/d$. In fact, based on scaling arguments it is easy to argue that for $m > 2 - 2/d$, the diffusion term dominates when density becomes large, leading to global existence of solutions for all masses. This result was shown in [63] together with the global uniform bound of solutions for all times.

However, in all cases where the diffusion dominates over the aggregation, the long time asymptotics of solutions to (1.1) have not been clarified, as pointed out in [7]. Are there stationary solutions for all masses when the diffusion term dominates? And if so, are they unique up to translations? Do they determine the long time asymptotics for (1.1)? Only partial answers to these questions are present in the literature, which we summarize below.

To show the existence of stationary solutions to (1.1), a natural idea is to look for the global minimizer of its associated free energy functional (1.2). For the 3D case with Newtonian interaction potential and $m > 4/3$, Lions' concentration-compactness principle [52] gives the existence of a global minimizer of (1.2) for any given mass. The argument can be extended to kernels that are no more singular than Newtonian potential in \mathbb{R}^d at the origin, and have slow decay at infinity. The existence result is further generalized by [4] to a broader classes of kernels, which can have faster decay at infinity. In all the above cases, the global minimizer of (1.2) corresponds to a stationary solution to (1.1) in the sense of distributions. In addition, the global minimizer must be radially decreasing due to Riesz's rearrangement theorem.

Regarding the uniqueness of stationary solutions to (1.1), most of the available results are for Newtonian interaction. For the 3D Newtonian potential with $m > 4/3$, for any given mass, the authors in [50] prove uniqueness of stationary solutions to (1.1) among radial functions, and their method can be generalized to the Newtonian potential in \mathbb{R}^d with $m > 2 - 2/d$. For the 3D case with $m > 4/3$, [62] show that all compactly supported stationary solutions must be radial up to a translation, hence obtaining uniqueness of stationary solutions among compactly supported functions. The proof is based on moving plane techniques, where the compact support of the stationary solution seems crucial, and it also relies on the fact that the Newtonian potential in 3D converges to zero at infinity. Similar results are obtained in [22] for 2D Newtonian potential with $m > 1$ using an adapted moving plane technique. Again, the uniqueness result is based on showing radial symmetry of compactly supported stationary solutions. Finally, we mention that

uniqueness of stationary states has been proved for general attracting kernels in one dimension in the case $m = 2$, see [17]. To the best of our knowledge, even for Newtonian potential, we are not aware of any results showing that all stationary solutions are radial (up to a translation).

Previous results show the limitations of the present theory: although the existence of stationary states for all masses is obtained for quite general potentials, their uniqueness, crucial for identifying the long time asymptotics, is only known in very particular cases of diffusive dominated problems. The available uniqueness results are not very satisfactory due to the compactly supported restriction on the uniqueness class imposed by the moving plane techniques. And thus, large time asymptotics results are not at all available due to the lack of mass confinement results of any kind uniformly in time together with the difficulty of identifying the long time limits of sequences of solutions due to the restriction on the uniqueness class for stationary solutions.

If one wants to show that the long time asymptotics are uniquely determined by the initial mass and center of mass, a clear strategy used in many other nonlinear diffusion problems, see [70] and the references therein, is the following: one first needs to prove that all stationary solutions are radial up to a translation in a non restrictive class of stationary solutions, then one has to show uniqueness of stationary solutions among radial solutions, and finally this uniqueness will allow to identify the limits of time diverging sequences of solutions, if compactness of these sequences is shown in a suitable functional framework. Let us point out that comparison arguments used in standard porous medium equations are out of the question here due to the lack of maximum principle by the presence of the nonlocal term.

In this work, we will give the first full result of long time asymptotics for a diffusion dominated problem using the previous strategy without smallness assumptions of any kind. More precisely, we will prove that all solutions to the 2D Keller-Segel equation with $m > 1$ converge to the global minimizer of its free energy using the previous strategy. The first step will be to show radial symmetry of stationary solutions to (1.1) under quite general assumptions on W and the class of stationary solutions. Let us point out that standard rearrangement techniques fail in trying to show radial symmetry of general stationary states to (1.1) and they are only useful for showing radial symmetry of global minimizers, see [22]. Comparison arguments for radial solutions allow to prove uniqueness of radial stationary solutions in particular cases [50, 46]. However, up to our knowledge, there is no general result in the literature about radial symmetry of stationary solutions to nonlocal aggregation-diffusion equations.

Our first main result is that all stationary solutions of (1.1) are radially decreasing up to translation by a fully novel application of continuous Steiner symmetrization techniques for the problem (1.1). Continuous Steiner symmetrization has been used in calculus of variations [15] for replacing rearrangement inequalities [14, 49, 56], but its application to nonlinear nonlocal aggregation-diffusion PDEs is completely new. Most of the results present in the literature using continuous Steiner symmetrization deal with functionals of first order, i.e. functionals involving a power of the modulus of the gradient of the unknown, see [43, Section II] and [42, 15], while in our case the functional (1.2) is purely of zeroth order. The decay of the attractive Newtonian potential interaction term in $d \geq 3$ follows from [15, Corollary 2] and [56], which is the only result related to our strategy. We will construct a curve of measures using continuous Steiner symmetrization such that the functional (1.2) decays strictly along that curve unless the base point is radially symmetric. This fact together with the assumption that the base point is a stationary state leads to a contradiction unless the stationary state is radially symmetric. This first main result is the content of Section 2 in which we specify the assumptions on the interaction potential and the notion of stationary solutions in details. We point out that the variational structure of (1.1) is crucial to show the radially decreasing property of stationary solutions.

The result of radial symmetry for general stationary solutions to (1.1) is quite striking in comparison to other gradient flow models in collective behavior based on the competition of attractive

and repulsive effects via nonlocal interaction potentials. Actually, it is demonstrated both numerically and asymptotically in [47, 6, 3] that there should be stationary solutions of these fully nonlocal interaction models which are not radially symmetric despite the radial symmetry of the interaction potential. Our first main result shows that this break of symmetry does not happen whenever nonlinear diffusion is chosen to model very strong localized repulsion forces, see [67]. Another consequence of our radial symmetry results is the lack of non-radial local minimizers of the free energy functional (1.2) which is not all obvious.

We next study more properties of particular radially decreasing stationary solutions. We make use of the variational structure to show the existence of global minimizers to (1.2) under very general hypotheses on the interaction potential W . In section 3, we show that these global minimizers are in fact compactly supported radially decreasing continuous functions. These results fully generalize the results in [62, 22]. Putting together Sections 2 and 3, the uniqueness and full characterization of the stationary states is reduced to uniqueness among the class of radial solutions. This result is known in the case of Newtonian attraction kernels [50].

Finally, we make use of the uniqueness among translations for any given mass of stationary solutions to (1.1) to obtain the second main result of this work, namely to answer the open problem of the long time asymptotics to (1.1) with Newtonian interaction in 2D. This is accomplished in Section 4 by a compactness argument for which one has to extract the corresponding uniform in time bounds and a careful treatment of the nonlinear terms and dissipation while taking the limit $t \rightarrow \infty$. We do not know how to obtain a similar result for Newtonian interaction in $d \geq 3$ due to the lack of uniform in time mass confinement bounds in this case. We essentially cannot show that mass does not escape to infinity while taking the limit $t \rightarrow \infty$. However, the compactness and characterization of stationary solutions is still valid in that case.

The present work opens new perspectives to show radial symmetry for stationary solutions to nonlocal aggregation-diffusion problems. While the hypotheses of our result to ensure existence of global radially symmetric minimizers of (1.2), and in turn of stationary solutions to (1.1), are quite general, we do not know yet whether there is uniqueness among radially symmetric stationary solutions (with a fixed mass) for general non-Newtonian kernels. We even do not have available uniqueness results of radial minimizers beyond Newtonian kernels. Understanding if the existence of radially symmetric local minimizers, that are not global, is possible for functionals of the form (1.2) with radial interaction potential is thus a challenging question. Concerning the long-time asymptotics of (1.1), the lack of a novel approach to find confinement of mass beyond the usual virial techniques and comparison arguments in radial coordinates hinders the advance in their understanding even for Newtonian kernels with $d \geq 3$. Last but not least, our results open a window to obtain rates of convergence towards the unique equilibrium up to translation for the Newtonian kernel in 2D. The lack of general convexity of this variational problem could be compensated by recent results in a restricted class of functions, see [25]. However, the problem is quite challenging due to the presence of free boundaries in the evolution of compactly supported solutions to (1.1) that rules out direct linearization techniques as in the linear diffusion case [18].

2. RADIAL SYMMETRY OF STATIONARY STATES WITH DEGENERATE DIFFUSION

Throughout this section, we assume that $m > 1$, and W satisfies the following four assumptions:

(K1) W is attracting, i.e., $W(x) \in C^1(\mathbb{R}^d \setminus \{0\})$ is radially symmetric

$$W(x) = \omega(|x|) = \omega(r)$$

and $\omega'(r) > 0$ for all $r > 0$ with $\omega(1) = 0$.

(K2) W is no more singular than the Newtonian kernel in \mathbb{R}^d at the origin, i.e., there exists some $C_w > 0$ such that $\omega'(r) \leq C_w r^{1-d}$ for $r \leq 1$.

(K3) There exists some $C_w > 0$ such that $\omega'(r) \leq C_w$ for all $r > 1$.

(K4) Either $\omega(r)$ is bounded for $r \geq 1$ or there exists $C_w > 0$ such that for all $a, b \geq 0$:

$$\omega_+(a+b) \leq C_w(1 + \omega(1+a) + \omega(1+b)).$$

As usual, ω_{\pm} denotes the positive and negative part of ω such that $\omega = \omega_+ - \omega_-$. In particular, if $W = -\mathcal{N}$ is the attractive Newtonian potential, where \mathcal{N} is the fundamental solution of $-\Delta$ operator in \mathbb{R}^d , then W satisfies all the assumptions.

We denote by $L_+^1(\mathbb{R}^d)$ the set of all nonnegative functions in $L^1(\mathbb{R}^d)$. Let us start by defining precisely stationary states to the aggregation equation (1.1) with a potential satisfying (K1)-(K4).

Definition 2.1. Given $\rho_s \in L_+^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$ we call it a **stationary state** for the evolution problem (1.1) if $\rho_s^m \in H_{loc}^1(\mathbb{R}^d)$, $\nabla \psi_s := \nabla W * \rho_s \in L_{loc}^1(\mathbb{R}^d)$, and it satisfies

$$\nabla \rho_s^m = -\rho_s \nabla \psi_s \text{ in } \mathbb{R}^d \quad (2.1)$$

in the sense of distributions in \mathbb{R}^d .

Let us first note that $\nabla \psi_s$ is globally bounded under the assumptions (K1)-(K3). To see this, a direct decomposition in near- and far-field sets yields

$$\begin{aligned} |\nabla \psi_s(x)| &\leq \int_{\mathbb{R}^d} |\nabla W(x-y)| \rho_s(y) dy \leq C_w \int_{\mathcal{A}} \frac{1}{|x-y|^{d-1}} \rho_s(y) dy + C_w \int_{\mathcal{B}} \rho_s(y) dy \\ &\leq C_w \int_{\mathcal{A}} \frac{1}{|x-y|^{d-1}} dy \|\rho_s\|_{L^\infty(\mathbb{R}^d)} + C_w \|\rho_s\|_{L^1(\mathbb{R}^d)} \leq C(\|\rho_s\|_{L^1(\mathbb{R}^d)} + \|\rho_s\|_{L^\infty(\mathbb{R}^d)}). \end{aligned} \quad (2.2)$$

where we split the integrand into the sets $\mathcal{A} := \{y : |x-y| \leq 1\}$ and $\mathcal{B} := \mathbb{R}^d \setminus \mathcal{A}$, and apply the assumptions (K1)-(K3).

Under the additional assumptions (K4) and $\omega(1+|x|)\rho_s \in L^1(\mathbb{R}^d)$, we will show that the potential function $\psi_s(x) = W * \rho_s(x)$ is also locally bounded. First, note that (K1)-(K3) ensures that $|\omega(r)| \leq \tilde{C}_w \phi(r)$ for all $r \leq 1$ with some $\tilde{C}_w > 0$, where

$$\phi(r) := \begin{cases} r^{2-d} & \text{if } d \geq 3 \\ -\log(r) & \text{if } d = 2 \\ r-1 & \text{if } d = 1 \end{cases}. \quad (2.3)$$

Hence we can again perform a decomposition in near- and far-field sets and obtain

$$\begin{aligned} |\psi_s(x)| &\leq \int_{\mathbb{R}^d} |W(x-y)| \rho_s(y) dy \leq C_w \int_{\mathcal{A}} \phi(|x-y|) \rho_s(y) dy + \int_{\mathcal{B}} \omega_+(|x|+|y|) \rho_s(y) dy \\ &\leq C_w \int_{\mathcal{A}} \phi(|x-y|) dy \|\rho_s\|_{L^\infty(\mathbb{R}^d)} + C_w(1 + \omega(1+|x|)) \|\rho_s\|_{L^1(\mathbb{R}^d)} + C_w \|\omega(1+|x|)\rho_s\|_{L^1(\mathbb{R}^d)} \\ &\leq C(\|\rho_s\|_{L^1(\mathbb{R}^d)} + \|\rho_s\|_{L^\infty(\mathbb{R}^d)}) + \omega(1+|x|) \|\rho_s\|_{L^1(\mathbb{R}^d)} + C_w \|\omega(1+|x|)\rho_s\|_{L^1(\mathbb{R}^d)}. \end{aligned} \quad (2.4)$$

Our main goal in this section is the following theorem.

Theorem 2.2. Assume that W satisfies (K1)-(K4). Let $\rho_s \in L_+^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$ with $\omega(1+|x|)\rho_s \in L^1(\mathbb{R}^d)$ be a non-negative stationary state of (1.1) in the sense of Definition 2.1. Then ρ_s must be radially decreasing up to a translation, i.e. there exists some $x_0 \in \mathbb{R}^d$, such that $\rho_s(\cdot - x_0)$ is radially symmetric, and $\rho_s(|x - x_0|)$ is non-increasing in $|x - x_0|$.

Before going into the details of the proof, we briefly outline the strategy here. Assume there is a stationary state ρ_s which is **not** radially decreasing under any translation. To obtain a contradiction, we consider the free energy functional $\mathcal{E}[\rho]$ associated with (1.1),

$$\mathcal{E}[\rho] = \frac{1}{m-1} \int_{\mathbb{R}^d} \rho^m dx + \frac{1}{2} \int_{\mathbb{R}^d} \rho(W * \rho) dx =: \mathcal{S}[\rho] + \mathcal{I}[\rho]. \quad (2.5)$$

We first observe that the energy of the steady state ρ_s is finite since the potential function $\psi_s = W * \rho_s \in \mathcal{W}_{loc}^{1,\infty}(\mathbb{R}^d)$ satisfies (2.4) with $\omega(1+|x|)\rho_s \in L^1(\mathbb{R}^d)$. Using the assumption that ρ_s is not

radially decreasing under any translation, we will apply the continuous Steiner symmetrization to perturb around ρ_s and construct a continuous family of densities $\mu(\tau, \cdot)$ with $\mu(0, \cdot) = \rho_s$, such that $\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s] < -c\tau$ for some $c > 0$ and any small $\tau > 0$. On the other hand, using that ρ_s is a stationary state, we will show that $|\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s]| \leq C\tau^2$ for some $C > 0$ and any small $\tau > 0$. Combining these two inequalities together gives us a contradiction for sufficiently small $\tau > 0$.

Let us characterize first the set of possible stationary states of (1.1) in the sense of Definition 2.1 and their regularity. Parts of these arguments are reminiscent from those done in [62, 22] in the case of attractive Newtonian potentials.

Lemma 2.3. *Let $\rho_s \in L^1_+(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$ with $\omega(1 + |x|)\rho_s \in L^1(\mathbb{R}^d)$ be a non-negative stationary state of (1.1) in the sense of Definition 2.1. Then $\rho_s \in C(\mathbb{R}^d)$, and there exists some $C = C(\|\rho_s\|_{L^1}, \|\rho_s\|_{L^\infty}, C_w, d) > 0$, such that*

$$|\nabla(\rho_s^{m-1})| \leq C \quad \text{in supp } \rho_s.$$

Proof. We have already checked that under these assumptions on W and ρ_s , the potential function $\psi_s \in \mathcal{W}_{loc}^{1,\infty}(\mathbb{R}^d)$ due to (2.2)-(2.4). Since $\rho_s^m \in H_{loc}^1(\mathbb{R}^d)$, then ρ_s^m is a weak $H_{loc}^1(\mathbb{R}^d)$ solution of

$$\Delta \rho_s^m = -\nabla \cdot (\rho_s \nabla \psi_s) \quad \text{in } \mathbb{R}^d \quad (2.6)$$

with right hand side belonging to $\mathcal{W}_{loc}^{-1,p}(\mathbb{R}^d)$ for all $1 \leq p \leq \infty$. As a consequence, ρ_s^m is in fact a weak solution in $\mathcal{W}_{loc}^{1,p}(\mathbb{R}^d)$ for all $1 < p < \infty$ of (2.6) by classical elliptic regularity results. Sobolev embedding shows that ρ_s^m belongs to some Hölder space $C_{loc}^{0,\alpha}(\mathbb{R}^d)$, and thus $\rho_s \in C_{loc}^{0,\alpha/m}(\mathbb{R}^d)$. Let us define the set $\Omega = \{x \in \mathbb{R}^d : \rho_s(x) > 0\}$. Since $\rho_s \in C(\mathbb{R}^d)$, then Ω is an open set and it consists of a countable number of open possibly unbounded connected components. Let us take any bounded smooth connected open subset Θ such that $\bar{\Theta} \subset \Omega$. Since $\rho_s \in C(\mathbb{R}^d)$, then ρ_s is bounded away from zero in Θ and thus due to the assumptions on ρ_s , we have that $\nabla \rho_s^{m-1} = \frac{m-1}{m\rho_s} \nabla \rho_s^m$ holds in the distributional sense in Θ . We conclude that wherever ρ_s is positive, (2.1) can be interpreted as

$$\nabla \left(\frac{m}{m-1} \rho_s^{m-1} + \psi_s \right) = 0, \quad (2.7)$$

in the sense of distributions in Ω . Hence, the function $G(x) = \frac{m}{m-1} \rho_s^{m-1}(x) + \psi_s(x)$ is constant in each connected component of Ω . From here, we deduce that any stationary state of (1.1) in the sense of Definition 2.1 is given by

$$\rho_s(x) = \left(\frac{m-1}{m} (G - \psi_s)(x) \right)_+^{\frac{1}{m-1}}, \quad (2.8)$$

where $G(x)$ is a constant in each connected component of the support of ρ_s , and its value may differ in different connected components. Due to $\psi_s \in \mathcal{W}_{loc}^{1,\infty}(\mathbb{R}^d)$, we deduce that $\rho_s \in C_{loc}^{0,1/(m-1)}(\mathbb{R}^d)$ if $m \geq 2$ and $\rho_s \in C_{loc}^{0,1}(\mathbb{R}^d)$ for $1 < m < 2$. Putting together (2.7) and (2.4), we conclude the desired estimate. \square

2.1. Some preliminaries about rearrangements. Now we briefly recall some standard notions and basic properties of decreasing rearrangements for nonnegative functions that will be used later. For a deeper treatment of these topics, we address the reader to the books [37, 5, 41, 45, 49] or the papers [64, 65, 66, 57]. We denote by $|E|_d$ the Lebesgue measure of a measurable set E in \mathbb{R}^d . Moreover, the set $E^\#$ is defined as the ball centered at the origin such that $|E^\#|_d = |E|_d$.

A nonnegative measurable function f defined on \mathbb{R}^d is called *radially symmetric* if there is a nonnegative function \tilde{f} on $[0, \infty)$ such that $f(x) = \tilde{f}(|x|)$ for all $x \in \mathbb{R}^d$. If f is radially symmetric, we will often write $f(x) = f(r)$ for $r = |x| \geq 0$ by a slight abuse of notation. We say that f is *rearranged* if it is radial and \tilde{f} is a nonnegative right-continuous, non-increasing function of $r > 0$. A similar definition can be applied for real functions defined on a ball $B_R(0) = \{x \in \mathbb{R}^d : |x| < R\}$.

We define the *distribution function* of $f \in L^1_+(\mathbb{R}^d)$ by

$$\zeta_f(\tau) = |\{x \in \mathbb{R}^d : f(x) > \tau\}|_d, \quad \text{for all } \tau > 0.$$

Then the function $f^* : [0, +\infty) \rightarrow [0, +\infty]$ defined by

$$f^*(s) = \sup\{\tau > 0 : \zeta_f(\tau) > s\}, \quad s \in [0, +\infty),$$

will be called the *Hardy-Littlewood one-dimensional decreasing rearrangement* of f . By this definition, one could interpret f^* as the generalized right-inverse function of $\zeta_f(\tau)$.

Making use of the definition of f^* , we can define a special radially symmetric decreasing function $f^\#$, which we will call the *Schwarz spherical decreasing rearrangement* of f by means of the formula

$$f^\#(x) = f^*(\omega_d |x|^d) \quad x \in \mathbb{R}^d, \quad (2.9)$$

where ω_d is the volume of the unit ball in \mathbb{R}^d . It is clear that if the set $\Omega_f = \{x \in \mathbb{R}^d : f(x) > 0\}$ of f has finite measure, then $f^\#$ is supported in the ball $\Omega_f^\#$.

One can show that f^* (and so $f^\#$) is equidistributed with f (*i.e.* they have the same distribution function). Thus if $f \in L^p(\mathbb{R}^d)$, a simple use of Cavalieri's principle (see *e.g.* [65, 45]) leads to the invariance property of the L^p norms:

$$\|f\|_{L^p(\mathbb{R}^d)} = \|f^*\|_{L^p(0, \infty)} = \|f^\#\|_{L^p(\mathbb{R}^d)} \quad \text{for all } 1 \leq p \leq \infty. \quad (2.10)$$

In particular, using the layer-cake representation formula (see *e.g.* [49]) one could easily infer that

$$f^\#(x) = \int_0^\infty \chi_{\{f > \tau\}^\#} d\tau.$$

Among the many interesting properties of rearrangements, it is worth mentioning the *Hardy-Littlewood inequality* (see [37, 5, 45] for the proof): for any couple of nonnegative measurable functions f, g on \mathbb{R}^d , we have

$$\int_{\mathbb{R}^d} f(x)g(x)dx \leq \int_{\mathbb{R}^d} f^\#(x)g^\#(x)dx. \quad (2.11)$$

Since in Section 4 we will use estimates of the solutions Keller-Segel problems in terms of their integrals, let us now recall the concept of comparison of mass concentration, taken from [68], that is remarkably useful.

Definition 2.4. Let $f, g \in L^1_{loc}(\mathbb{R}^d)$ be two nonnegative, radially symmetric functions on \mathbb{R}^d . We say that f is less concentrated than g , and we write $f \prec g$ if for all $R > 0$ we get

$$\int_{B_R(0)} f(x)dx \leq \int_{B_R(0)} g(x)dx.$$

The partial order relationship \prec is called *comparison of mass concentrations*. Of course, this definition can be suitably adapted if f, g are radially symmetric and locally integrable functions on a ball B_R . The comparison of mass concentrations enjoys a nice equivalent formulation if f and g are rearranged, whose proof we refer to [1, 69]:

Lemma 2.5. Let $f, g \in L^1_+(\mathbb{R}^d)$ be two nonnegative rearranged functions. Then $f \prec g$ if and only if for every convex nondecreasing function $\Phi : [0, \infty) \rightarrow [0, \infty)$ with $\Phi(0) = 0$ we have

$$\int_{\Omega} \Phi(f(x)) dx \leq \int_{\Omega} \Phi(g(x)) dx.$$

From this Lemma, it easily follows that if $f \prec g$ and $f, g \in L^p(\mathbb{R}^d)$ are rearranged and non-negative, then

$$\|f\|_{L^p(\mathbb{R}^d)} \leq \|g\|_{L^p(\mathbb{R}^d)} \quad \forall p \in [1, \infty].$$

Let us also observe that if $f, g \in L_+^1(\mathbb{R}^d)$ are nonnegative and rearranged, then $f \prec g$ if and only if for all $s \geq 0$ we have

$$\int_0^s f^*(\sigma) d\sigma \leq \int_0^s g^*(\sigma) d\sigma. \quad (2.12)$$

If $f \in L_+^1(\mathbb{R}^d)$, we denote by $M_2[f]$ the second moment of f , i.e.

$$M_2[f] := \int_{\mathbb{R}^d} f(x) |x|^2 dx. \quad (2.13)$$

In this regard, another interesting property which will turn out useful is the following

Lemma 2.6. *Let $f, g \in L_+^1(\mathbb{R}^d)$ with $\|f\|_{L^1(\mathbb{R}^d)} = \|g\|_{L^1(\mathbb{R}^d)}$. If additionally g is rearranged and $f^\# \prec g$, then $M_2[f] \geq M_2[g]$.*

Proof. Let us consider the sequence of bounded radially increasing functions $\{\varphi_n\}$, where $\varphi_n(x) = \min\{|x|^2, n\}$ is the truncation of the function $|x|^2$ at the level n and define the function

$$h_n = n - \varphi_n.$$

Then h_n is nonnegative, bounded and rearranged. Thus using the Hardy-Littlewood inequality (2.11) and [1, Corollary 2.1] we find

$$\begin{aligned} \int_{\mathbb{R}^d} f(x) \varphi_n(x) dx &= n \|f\|_{L^1(\mathbb{R}^d)} - \int_{\mathbb{R}^d} f(x) h_n(x) dx \geq n \|f\|_{L^1(\mathbb{R}^d)} - \int_{\mathbb{R}^d} f^\#(x) h_n(x) dx \\ &\geq n \|g\|_{L^1(\mathbb{R}^d)} - \int_{\mathbb{R}^d} g(x) h_n(x) dx = \int_{\mathbb{R}^d} g(x) \varphi_n(x) dx \end{aligned}$$

Then passing to the limit as $n \rightarrow \infty$ we find the desired result. \square

2.2. Continuous Steiner symmetrization. Although classical decreasing rearrangement techniques are very useful to study properties of the minimizers and for solutions of the evolution problem (1.1) in next sections, we do not know how to use them in connection with showing that stationary states are radially symmetric. For an introduction of continuous Steiner symmetrization and its properties, see [14, 15, 49]. In this subsection, we will use continuous Steiner symmetrization to prove the following proposition.

Proposition 2.7. *Let $\mu_0 \in C(\mathbb{R}^d) \cap L_+^1(\mathbb{R}^d)$, and assume it is **not** radially decreasing after any translation. Moreover, assume that there exist some $C_0 > 0$ and $m > 1$, such that $|\nabla \mu_0^{m-1}| \leq C_0$ in $\text{supp } \mu_0$. Then there exist some $\delta_0 > 0, c_0 > 0, C_1 > 0$ (depending on μ_0 and W) and a function $\mu \in C([0, \delta_0] \times \mathbb{R}^d)$ with $\mu(0, \cdot) = \mu_0$, such that μ satisfies the following for a short time $\tau \in [0, \delta_0]$, where \mathcal{E} is as given in (2.5):*

$$\mathcal{E}[\mu(\tau)] \leq \mathcal{E}[\mu_0] - c_0 \tau, \quad (2.14)$$

$$|\mu(\tau, x) - \mu_0(x)| \leq C_1 \mu_0(x) \tau \quad \text{for all } x \in \mathbb{R}^d, \quad (2.15)$$

$$\int_{D_i} \mu(\tau, x) - \mu_0(x) dx = 0 \quad \text{for any connected component } D_i \text{ of } \text{supp } \mu_0. \quad (2.16)$$

2.2.1. Definitions and basic properties of Steiner symmetrization. Let us first introduce the concept of Steiner symmetrization for a measurable set $E \subset \mathbb{R}^d$. If $d = 1$, the Steiner symmetrization of E is the symmetric interval $S(E) = \{x \in \mathbb{R} : |x| < |E|_1/2\}$. Now we want to define the Steiner symmetrization of E with respect to a direction in \mathbb{R}^d for $d \geq 2$. The direction we symmetrize corresponds to the unit vector $e_1 = (1, 0, \dots, 0)$, although the definition can be modified accordingly when considering any other direction in \mathbb{R}^d .

Let us label a point $x \in \mathbb{R}^d$ by (x_1, x') , where $x' = (x_2, \dots, x_d) \in \mathbb{R}^{d-1}$ and $x_1 \in \mathbb{R}$. Given any measurable subset E of \mathbb{R}^d we define, for all $x' \in \mathbb{R}^{d-1}$, the *section* of E with respect to the direction x_1 as the set

$$E_{x'} = \{x_1 \in \mathbb{R} : (x_1, x') \in E\}.$$

Then we define the Steiner symmetrization of E with respect to the direction x_1 as the set $S(E)$ which is symmetric about the hyperplane $\{x_1 = 0\}$ and is defined by

$$S(E) = \{(x_1, x') \in \mathbb{R}^d : x_1 \in S(E_{x'})\}.$$

In particular we have that $|E|_d = |S(E)|_d$.

Now, consider a non-negative function $\mu_0 \in L^1(\mathbb{R}^d)$, for $d \geq 2$. For all $x' \in \mathbb{R}^{d-1}$, let us consider the distribution function of $\mu_0(\cdot, x')$, i.e. the function

$$\zeta_{\mu_0}(h, x') = |U_{x'}^h|_1 \quad \text{for all } h > 0, x' \in \mathbb{R}^{d-1},$$

where

$$U_{x'}^h = \{x_1 \in \mathbb{R} : \mu_0(x_1, x') > h\}. \quad (2.17)$$

Then we can give the following definition:

Definition 2.8. We define the Steiner symmetrization (or Steiner rearrangement) of μ_0 in the direction x_1 as the function $S\mu_0 = S\mu_0(x_1, x')$ such that $S\mu_0(\cdot, x')$ is exactly the Schwarz rearrangement of $\mu_0(\cdot, x')$ i.e. (see (2.9))

$$S\mu_0(x_1, x') = \sup \{h > 0 : \zeta_{\mu_0}(h, x') > 2|x_1|\}.$$

As a consequence, the Steiner symmetrization $S\mu_0(x_1, x')$ is a function being symmetric about the hyperplane $\{x_1 = 0\}$ and for each $h > 0$ the level set

$$\{(x_1, x') : S\mu_0(x_1, x') > h\}$$

is equivalent to the Steiner symmetrization

$$S(\{(x_1, x') : \mu_0(x_1, x') > h\})$$

which implies that $S\mu_0$ and μ_0 are equidistributed, yielding the invariance of the L^p norms when passing from μ_0 to $S\mu_0$, that is for all $p \in [1, \infty]$ we have

$$\|S\mu_0\|_{L^p(\mathbb{R}^d)} = \|\mu_0\|_{L^p(\mathbb{R}^d)}.$$

Moreover, by the layer-cake representation formula, we have

$$S\mu_0(x_1, x') = \int_0^\infty \chi_{S(U_{x'}^h)}(x_1) dh. \quad (2.18)$$

Now, we introduce a continuous version of this Steiner procedure via an interpolation between a set or a function and their Steiner symmetrizations that we will use in our symmetry arguments for steady states.

Definition 2.9. For an open set $U \subset \mathbb{R}$, we define its continuous Steiner symmetrization $M^\tau(U)$ for any $\tau \geq 0$ as below. In the following we abbreviate an open interval $(c-r, c+r)$ by $I(c, r)$, and we denote by $\text{sgn } c$ the sign of c (which is 1 for positive c , -1 for negative c , and 0 if $c = 0$).

(1) If $U = I(c, r)$, then

$$M^\tau(U) := \begin{cases} I(c - \tau \text{sgn } c, r) & \text{for } 0 \leq \tau < |c|, \\ I(0, r) & \text{for } \tau \geq |c|. \end{cases}$$

(2) If $U = \cup_{i=1}^N I(c_i, r_i)$ (where all $I(c_i, r_i)$ are disjoint), then $M^\tau(U) := \cup_{i=1}^N M^\tau(I(c_i, r_i))$ for $0 \leq \tau < \tau_1$, where τ_1 is the first time two intervals $M^\tau(I(c_i, r_i))$ share a common endpoint. Once this happens, we merge them into one open interval, and repeat this process starting from $\tau = \tau_1$.

(3) If $U = \cup_{i=1}^\infty I(c_i, r_i)$ (where all $I(c_i, r_i)$ are disjoint), let $U_N = \cup_{i=1}^N I(c_i, r_i)$ for each $N > 0$, and define $M^\tau(U) := \cup_{N=1}^\infty M^\tau(U_N)$.

See Figure 1 for illustrations of $M^\tau(U)$ in the cases (1) and (2). Also, we point out that case (3) can be seen as a limit of case (2), since for each $N_1 < N_2$ one can easily check that $M^\tau(U_{N_1}) \subset M^\tau(U_{N_2})$ for all $\tau \geq 0$. Moreover, according to [15], the definition of $M^\tau(U)$ can be extended to any measurable set U of \mathbb{R} , since

$$U = \bigcap_{n=1}^{\infty} O_n \setminus N,$$

being $O_n \supset O_{n+1}$ $n = 1, 2, \dots$, open sets and N a nullset.

FIGURE 1. Illustrations of $M^\tau(U)$ when U is a single open interval (left), and when U is the union of two open intervals (right).

In the next lemma we state four simple facts about M^τ . They can be easily checked for case (1) and (2) (hence true for (3) as well by taking the limit), and we omit the proof.

Lemma 2.10. *Given any open set $U \subset \mathbb{R}$, let $M^\tau(U)$ be defined in Definition 2.9. Then*

- (a) $M^0(U) = U$, $M^\infty(U) = S(E)$.
- (b) $|M^\tau(U)| = |U|$ for all $\tau \geq 0$.
- (c) If $U_1 \subset U_2$, we have $M^\tau(U_1) \subset M^\tau(U_2)$ for all $\tau \geq 0$.
- (d) M^τ has the semigroup property: $M^{\tau+s}U = M^\tau(M^s(U))$ for any $\tau, s \geq 0$ and open set U .

Once we have the continuous Steiner symmetrization for a one-dimensional set, we can define the continuous Steiner symmetrization (in a certain direction) for a non-negative function in \mathbb{R}^d .

Definition 2.11. *Given $\mu_0 \in L^1_+(\mathbb{R}^d)$, we define its continuous Steiner symmetrization $S^\tau \mu_0$ (in direction $e_1 = (1, 0, \dots, 0)$) as follows. For any $x_1 \in \mathbb{R}, x' \in \mathbb{R}^{d-1}, h > 0$, let*

$$S^\tau \mu_0(x_1, x') := \int_0^\infty \chi_{M^\tau(U_{x'}^h)}(x_1) dh,$$

where $U_{x'}^h$ is defined in (2.17).

For an illustration of $S^\tau \mu_0$ for $\mu_0 \in L^1(\mathbb{R})$, see Figure 2.

Using the above definition, Lemma (2.10) and the representation (2.18) one immediately has

$$S^0 \mu_0 = \mu_0, \quad S^\infty \mu_0 = S \mu_0.$$

Furthermore, it is easy to check that $S^\tau \mu_0 = \mu_0$ for all τ if and only if μ_0 is symmetric decreasing about the hyperplane $H = \{x_1 = 0\}$. Below is the definition for a function being symmetric decreasing about a hyperplane:

Definition 2.12. *Let $\mu_0 \in L^1_+(\mathbb{R}^d)$. For a hyperplane $H \subset \mathbb{R}^d$ (with normal vector e), we say μ_0 is symmetric decreasing about H if for any $x \in H$, the function $f(\tau) := \mu_0(x + \tau e)$ is rearranged, i.e. if $f = f^\#$.*

FIGURE 2. Illustrations of μ_0 and $S^\tau \mu_0$ (for a small $\tau > 0$).

Next we state some basic properties of S^τ without proof, see [15, 41, 43] for instance.

Lemma 2.13. *The continuous Steiner symmetrization $S^\tau \mu_0$ in Definition 2.11 has the following properties:*

- (a) *For any $h > 0$, $|\{S^\tau \mu_0 > h\}| = |\{\mu_0 > h\}|$. As a result, $\|S^\tau \mu_0\|_{L^p(\mathbb{R}^d)} = \|\mu_0\|_{L^p(\mathbb{R}^d)}$ for all $1 \leq p \leq +\infty$.*
- (b) *S^τ has the semigroup property, that is, $S^{\tau+s} \mu_0 = S^\tau(S^s \mu_0)$ for any $\tau, s \geq 0$ and non-negative $\mu_0 \in L^1(\mathbb{R}^d)$.*

Lemma 2.13 immediately implies that $\mathcal{S}[S^\tau \mu_0]$ is constant in τ , where $\mathcal{S}[\cdot]$ is as given in (2.5).

2.2.2. Interaction energy under Steiner symmetrization. In this subsection, we will investigate $\mathcal{I}[S^\tau \mu_0]$. It has been shown in [15, Corollary 2] and [49, Theorem 3.7] that $\mathcal{I}[S^\tau \mu_0]$ is non-increasing in τ . Indeed, in the case that μ_0 is a characteristic function χ_{Ω_0} , it is shown in [56] that $\mathcal{I}[S^\tau \mu_0]$ is strictly decreasing for τ small enough if Ω_0 is not a ball. However, in order to obtain (2.14) for a strictly positive c_0 , some refined estimates are needed, and we will prove the following:

Proposition 2.14. *Let $\mu_0 \in C(\mathbb{R}^d) \cap L^1_+(\mathbb{R}^d)$. Assume the hyperplane $H = \{x_1 = 0\}$ splits the mass of μ_0 into half and half, and μ_0 is **not** symmetric decreasing about H . Let $\mathcal{I}[\cdot]$ be given in (2.5), where W satisfies the assumptions (K1)-(K3). Then $\mathcal{I}[S^\tau \mu_0]$ is non-increasing in τ , and there exists some $\delta_0 > 0$ (depending on μ_0) and $c_0 > 0$ (depending on μ_0 and W), such that*

$$\mathcal{I}[S^\tau \mu_0] \leq \mathcal{I}[\mu_0] - c_0 \tau \quad \text{for all } \tau \in [0, \delta_0].$$

The building blocks to prove Proposition 2.14 are a couple of lemmas estimating how the interaction energy between two *one-dimensional* densities μ_1, μ_2 changes under continuous Steiner symmetrization for each of them. That is, we will investigate how

$$I_{\mathcal{K}}[\mu_1, \mu_2](\tau) := \int_{\mathbb{R} \times \mathbb{R}} (S^\tau \mu_1)(x)(S^\tau \mu_2)(y) \mathcal{K}(x - y) dx dy \quad (2.19)$$

changes in τ for a given one dimensional kernel \mathcal{K} to be determined. We start with the basic case where μ_1, μ_2 are both characteristic functions of some open interval.

Lemma 2.15. *Assume $\mathcal{K}(x) \in C^1(\mathbb{R})$ is an even function with $\mathcal{K}'(x) < 0$ for all $x > 0$. For $i = 1, 2$, let $\mu_i := \chi_{I(c_i, r_i)}$ respectively, where $I(c, r)$ is as given in Definition 2.9. Then the following holds for the function $I(\tau) := I_{\mathcal{K}}[\mu_1, \mu_2](\tau)$ introduced in (2.19):*

- (a) $\frac{d^+}{d\tau} I(0) \geq 0$. (Here $\frac{d^+}{d\tau}$ stands for the right derivative.)
- (b) If in addition $\text{sgn } c_1 \neq \text{sgn } c_2$, then

$$\frac{d^+}{d\tau} I(0) \geq c_w \min\{r_1, r_2\} |c_2 - c_1| > 0, \quad (2.20)$$

where c_w is the minimum of $\mathcal{K}'(r)$ for $r \in [\frac{|c_2 - c_1|}{2}, r_1 + r_2 + |c_2 - c_1|]$.

Proof. By definition of S^τ , we have $S^\tau \mu_i = \chi_{M^\tau(I(c_i, r_i))}$ for $i = 1, 2$ and all $\tau \geq 0$. If $\text{sgn } c_1 = \text{sgn } c_2$, the two intervals $M^\tau(I(c_i, r_i))$ are moving towards the same direction for small enough τ , during which their interaction energy $I(\tau)$ remains constant, implying $\frac{d}{d\tau} I(0) = 0$. Hence it suffices to focus on $\text{sgn } c_1 \neq \text{sgn } c_2$ and prove (2.20).

Without loss of generality, we assume that $c_2 > c_1$, so that $\text{sgn } c_2 - \text{sgn } c_1$ is either 2 or 1. The definition of M^τ gives

$$\begin{aligned} I(\tau) &= \int_{-r_1 + c_1 - \tau \text{sgn } c_1}^{r_1 + c_1 - \tau \text{sgn } c_1} \int_{-r_2 + c_2 - \tau \text{sgn } c_2}^{r_2 + c_2 - \tau \text{sgn } c_2} \mathcal{K}(x - y) dy dx \\ &= \int_{-r_1}^{r_1} \int_{-r_2}^{r_2} \mathcal{K}(x - y + (c_1 - c_2) + \tau(\text{sgn } c_2 - \text{sgn } c_1)) dy dx. \end{aligned}$$

Taking its right derivative in τ yields

$$\frac{d^+}{d\tau} I(0) = (\text{sgn } c_2 - \text{sgn } c_1) \int_{-r_1}^{r_1} \int_{-r_2}^{r_2} \mathcal{K}'(x - y + (c_1 - c_2)) dy dx.$$

Let us deal with the case $r_1 \leq r_2$ first. In this case we rewrite $\frac{d^+}{d\tau} I(0)$ as

$$\frac{d^+}{d\tau} I(0) = (\text{sgn } c_2 - \text{sgn } c_1) \int_Q \mathcal{K}'(x - y) dx dy, \quad (2.21)$$

where Q is the rectangle $[-r_1, r_1] \times [-r_2 + (c_2 - c_1), r_2 + (c_2 - c_1)]$, as illustrated in Figure 3. Let $Q^- = Q \cap \{x - y > 0\}$, and $Q^+ = Q \cap \{x - y < 0\}$. The assumptions on \mathcal{K} imply $\mathcal{K}'(x - y) < 0$ in Q^- , and $\mathcal{K}'(x - y) > 0$ in Q^+ .

FIGURE 3. Illustration of the sets Q, Q^-, \tilde{Q}^+ and D in the proof of Lemma 2.15.

Let $\tilde{Q}^+ := Q^+ \cap \{y \leq r_2\}$, and $D := [-r_1, r_1] \times [r_2 + \frac{c_2 - c_1}{2}, r_2 + (c_2 - c_1)]$. (\tilde{Q}^+ and D are the yellow set and green set in Figure 3 respectively). By definition, \tilde{Q}^+ and D are disjoint subsets of Q^+ , so

$$\frac{d^+}{d\tau} I(0) \geq (\text{sgn } c_2 - \text{sgn } c_1) \left(\underbrace{\int_{Q^-} \mathcal{K}'(x - y) dx dy}_{\leq 0} + \underbrace{\int_{\tilde{Q}^+} \mathcal{K}'(x - y) dx dy}_{\geq 0} + \underbrace{\int_D \mathcal{K}'(x - y) dx dy}_{> 0} \right). \quad (2.22)$$

We claim that $\int_{Q^-} \mathcal{K}'(x - y) dx dy + \int_{\tilde{Q}^+} \mathcal{K}'(x - y) dx dy \geq 0$. To see this, note that $Q^- \cup \tilde{Q}^+$ forms a rectangle, whose center has a zero x -coordinate and a positive y -coordinate. Hence for any $h > 0$, the line segment $\tilde{Q}^+ \cup \{x - y = -h\}$ is longer than $Q^- \cup \{x - y = h\}$, which gives the claim.

Therefore, (2.22) becomes

$$\frac{d^+}{d\tau}I(0) \geq (\operatorname{sgn} c_2 - \operatorname{sgn} c_1) \int_D \mathcal{K}'(x-y) dx dy \geq \int_D \mathcal{K}'(x-y) dx dy \geq |D| \min_{(x,y) \in D} \mathcal{K}'(x-y)$$

Note that D is a rectangle with area $r_1(c_2 - c_1)$, and for any $(x, y) \in D$, we have $y - x \in [|c_2 - c_1|/2, r_1 + r_2 + |c_2 - c_1|]$. This finally gives

$$\frac{d^+}{d\tau}I(0) \geq r_1(c_2 - c_1) \min_{r \in [\frac{|c_2 - c_1|}{2}, r_1 + r_2 + |c_2 - c_1|]} |\mathcal{K}'(r)|.$$

Similarly, if $r_1 > r_2$, then $I'(0)$ can be written as (2.21) with \tilde{Q} defined as $[-r_1 + (c_2 - c_1), r_1 + (c_2 - c_1)] \times [-r_2, r_2]$ instead, and the above inequality would hold with the roles of r_1 and r_2 interchanged. Combining these two cases, we have

$$\frac{d^+}{d\tau}I(0) \geq c_w \min\{r_1, r_2\} |c_2 - c_1| \quad \text{for } \operatorname{sgn} c_1 \neq \operatorname{sgn} c_2,$$

where c_w is the minimum of $|\mathcal{K}'(r)|$ for $r \in [\frac{|c_2 - c_1|}{2}, r_1 + r_2 + |c_2 - c_1|]$. \square

The next lemma generalizes the above result to open sets with finite measures.

Lemma 2.16. *Assume $\mathcal{K}(x) \in C^1(\mathbb{R})$ is an even function with $\mathcal{K}'(r) < 0$ for all $r > 0$. For open sets $U_1, U_2 \subset \mathbb{R}$ with finite measure, let $\mu_i := \chi_{U_i}$ for $i = 1, 2$, and $I(\tau) := I_{\mathcal{K}}[\mu_1, \mu_2](\tau)$ is as defined in (2.19). Then*

- (a) $\frac{d}{d\tau}I(\tau) \geq 0$ for all $\tau \geq 0$;
- (b) *In addition, assume that there exists some $a \in (0, 1)$ and $R > \max\{|U_1|, |U_2|\}$ such that $|U_1 \cap (\frac{|U_1|}{2}, R)| > a$, and $|U_2 \cap (-R, -\frac{|U_2|}{2})| > a$. Then for all $\tau \in [0, a/4]$, we have*

$$\frac{d^+}{d\tau}I(\tau) \geq \frac{1}{128} c_w a^3 > 0, \tag{2.23}$$

where c_w is the minimum of $|\mathcal{K}'(r)|$ for $r \in [\frac{a}{4}, 4R]$.

Proof. It suffices to focus on the case when U_1, U_2 both consist of a finite disjoint union of open intervals, and for the general case we can take the limit. Recall that $S^\tau \mu_i = \chi_{M^\tau(U_i)}$ for $i = 1, 2$ and all $\tau \geq 0$.

To show (a), due to the semigroup property of S^τ in Lemma 2.13, all we need to show is $\frac{d^+}{d\tau}I(0) \geq 0$. By writing U_1, U_2 each as a union of disjoint open intervals and expressing $I(\tau)$ as a sum of the pairwise interaction energy, (a) immediately follows from Lemma 2.15(a).

We will prove (b) next. First, we claim that

$$A_1(\tau) := \left| M^\tau(U_1) \cap \left(\frac{|U_1|}{2} + \frac{a}{4}, R \right) \right| > \frac{a}{4} \quad \text{for all } \tau \in [0, \frac{a}{4}]. \tag{2.24}$$

To see this, note that $A_1(0) > \frac{3a}{4}$ due to the assumption $|U_1 \cap (\frac{|U_1|}{2}, R)| > a$. Since each interval in $M^\tau(U_1)$ moves with speed either 0 or ± 1 at each τ , we know $A_1'(\tau) \geq -2$ for all τ , yielding the claim. (Similarly, $A_2(\tau) := |M^\tau(U_2) \cap (-R, -\frac{|U_2|}{2} - \frac{a}{4})| > \frac{a}{4}$ for all $\tau \in [0, \frac{a}{4}]$.)

Now we pick any $\tau_0 \in [0, \frac{a}{4}]$, and we aim to prove (2.23) at this particular time τ_0 . At $\tau = \tau_0$, write $M^{\tau_0}(U_1) := \cup_{k=1}^{N_1} I(c_k^1, r_k^1)$, where all intervals $I(c_k^1, r_k^1)$ are disjoint, and none of them share common endpoints – if they do, we merge them into one interval.

Note that for every $x \in M^{\tau_0}(U_1) \cap (\frac{|U_1|}{2} + \frac{a}{4}, R)$, x must belong to some $I(c_k^1, r_k^1)$ with $a/4 \leq c_k^1 \leq R + |U_1|/2$. Otherwise, the length of $I(c_k^1, r_k^1)$ would exceed $|U_1|$, contradicting Lemma 2.10(a). We then define

$$\mathcal{J}_1 := \left\{ 1 \leq k \leq N_1 : \frac{a}{4} \leq c_k^1 \leq R + |U_1|/2 \right\}.$$

Combining the above discussion with (2.24), we have $\sum_{k \in \mathcal{J}_1} |I(c_k^1, r_k^1)| \geq a/4$, i.e.

$$\sum_{k \in \mathcal{J}_1} r_k^1 \geq \frac{a}{8}. \quad (2.25)$$

Likewise, let $M^{\tau_0}(U_2) := \cup_{k=1}^{N_2} I(c_k^2, r_k^2)$, and denote by \mathcal{J}_2 the set of indices k such that $-R - |U_2|/2 \leq c_k^2 \leq -\frac{a}{4}$, and similarly we have $\sum_{k \in \mathcal{J}_2} r_k^2 \geq a/8$.

The semigroup property of M^τ in Lemma 2.10 gives that for all $s > 0$,

$$M^{\tau_0+s}(U_1) = M^s(M^{\tau_0}(U_1)) = M^s(\cup_{k=1}^{N_1} I(c_k^1, r_k^1)).$$

Since none of the intervals $I(c_k^1, r_k^1)$ share common endpoints, we have

$$M^s(\cup_{k=1}^{N_1} I(c_k^1, r_k^1)) = \cup_{k=1}^{N_1} M^s(I(c_k^1, r_k^1)) \quad \text{for sufficiently small } s > 0.$$

A similar result holds for $M^{\tau_0+s}(U_2)$, hence we obtain for sufficiently small $s > 0$:

$$I(\tau_0 + s) = I_{\mathcal{K}}[\chi_{M^{\tau_0}(U_1)}, \chi_{M^{\tau_0}(U_2)}](s) = \sum_{k=1}^{N_1} \sum_{l=1}^{N_2} I_{\mathcal{K}}[\chi_{I(c_k^1, r_k^1)}, \chi_{I(c_l^2, r_l^2)}](s).$$

Applying Lemma 2.15(a) to the above identity yields

$$\frac{d^+}{d\tau} I(\tau_0) = \sum_{k=1}^{N_1} \sum_{l=1}^{N_2} \frac{d}{ds} I_{\mathcal{K}}[\chi_{I(c_k^1, r_k^1)}, \chi_{I(c_l^2, r_l^2)}] \Big|_{s=0} \geq \sum_{k \in \mathcal{J}_1} \sum_{l \in \mathcal{J}_2} \underbrace{\frac{d}{ds} I_{\mathcal{K}}[\chi_{I(c_k^1, r_k^1)}, \chi_{I(c_l^2, r_l^2)}] \Big|_{s=0}}_{=: T_{kl}}. \quad (2.26)$$

Next we will obtain a lower bound for T_{kl} . By definition of \mathcal{J}_1 and \mathcal{J}_2 , for each $k \in \mathcal{J}_1$ and $l \in \mathcal{J}_2$ we have that $c_k^1 \geq \frac{a}{4}$ and $c_l^2 \leq -\frac{a}{4}$, hence $|c_l^2 - c_k^1| \geq \frac{a}{2}$. Thus Lemma 2.15(b) yields

$$T_{kl} \geq c_w \min\{r_k^1, r_l^2\} |c_l^2 - c_k^1| \geq c_w \frac{a}{2} \min\{r_k^1, r_l^2\} \quad \text{for } k \in \mathcal{J}_1, l \in \mathcal{J}_2,$$

where $c_w = \min_{r \in [\frac{a}{4}, 4R]} |W'(r)|$. (Here we used that for $k \in \mathcal{J}_1, l \in \mathcal{J}_2$, we have $r_k^1 + r_l^2 + |c_l^2 - c_k^1| \leq |U_1|/2 + |U_2|/2 + (R + |U_1|/2) + (R + |U_2|/2) \leq 4R$, due to the assumption $R > \max\{|U_1|, |U_2|\}$.)

Plugging the above inequality into (2.26) and using $\min\{u, v\} \geq \min\{u, 1\} \min\{v, 1\}$ for $u, v > 0$, we have

$$\begin{aligned} \frac{d^+}{d\tau} I(\tau_0) &\geq \frac{ac_w}{2} \sum_{k \in \mathcal{J}_1} \sum_{l \in \mathcal{J}_2} \min\{r_k^1, 1\} \min\{r_l^2, 1\} \\ &= \frac{ac_w}{2} \left(\sum_{k \in \mathcal{J}_1} \min\{r_k^1, 1\} \right) \left(\sum_{l \in \mathcal{J}_2} \min\{r_l^2, 1\} \right) \\ &\geq \frac{ac_w}{2} \min \left\{ 1, \sum_{k \in \mathcal{J}_1} r_k^1 \right\} \min \left\{ 1, \sum_{l \in \mathcal{J}_2} r_l^2 \right\} \\ &\geq \frac{ac_w}{2} \min \left\{ 1, \frac{a}{8} \right\}^2 \geq \frac{1}{128} c_w a^3, \end{aligned}$$

here we applied (2.25) in the second-to-last inequality, and used the assumption $a \in (0, 1)$ for the last inequality. Since $\tau_0 \in [0, a/4]$ is arbitrary, we can conclude. \square

Now we are ready to prove Proposition 2.14.

Proof of Proposition 2.14. Since $\mu_0 \in C(\mathbb{R}^d) \cap L_+^1(\mathbb{R}^d)$ is *not* symmetric decreasing about $H = \{x_1 = 0\}$, we know that there exists some $x' \in \mathbb{R}^{d-1}$ and $h > 0$, such that $U_{x'}^h := \{x_1 \in \mathbb{R} : \mu_0(x_1, x') > h\}$ has finite measure, and its difference from $(-|U_{x'}^h|/2, |U_{x'}^h|/2)$ has nonzero measure.

For $R > 0, a > 0$, define

$$B_1^{R,a} = \{(x', h) \in \mathbb{R}^{d-1} \times (0, +\infty) : |U_{x'}^h \cap (|U_{x'}^h|/2, R)| > a, |x'| \leq R\},$$

$$B_2^{R,a} = \{(x', h) \in \mathbb{R}^{d-1} \times (0, +\infty) : |U_{x'}^h \cap (-R, -|U_{x'}^h|/2)| > a, |x'| \leq R\}.$$

Our discussion above yields that at least one of $B_1^{R,a}$ and $B_2^{R,a}$ is nonempty when R is sufficiently large and $a > 0$ sufficiently small (hence at least one of them must have nonzero measure by continuity of μ_0). Indeed, using the fact that H splits the mass of μ_0 into half and half, we can choose R sufficiently large and $a > 0$ sufficiently small (both of them depend on μ_0 only), such that both $B_1^{R,a}$ and $B_2^{R,a}$ have nonzero measure in $\mathbb{R}^{d-1} \times (0, +\infty)$.

Now, let us define a one-dimensional kernel $K_l(r) := -\frac{1}{2}W(\sqrt{r^2 + l^2})$. Note that for any $l > 0$, the kernel $K_l \in C^1(\mathbb{R})$ is even in r , and $K'_l(r) < 0$ for all $r > 0$. By definition of S^τ , we can rewrite $\mathcal{I}[S^\tau \mu_0]$ as

$$\mathcal{I}[S^\tau \mu_0] = - \int_{(\mathbb{R}^+)^2} \int_{\mathbb{R}^{2(d-1)}} \int_{\mathbb{R}^2} \chi_{M^\tau(U_{x'}^{h_1})}(x_1) \chi_{M^\tau(U_{y'}^{h_2})}(y_1) K_{|x'-y'|}(|x_1 - y_1|) dx_1 dy_1 dx' dy' dh_1 dh_2.$$

Thus using the notation in (2.19), $\mathcal{I}[S^\tau \mu_0]$ can be rewritten as

$$\mathcal{I}[S^\tau \mu_0] = - \int_{(\mathbb{R}^+)^2} \int_{\mathbb{R}^{2(d-1)}} I_{K_{|x'-y'|}}[\chi_{U_{x'}^{h_1}}, \chi_{U_{y'}^{h_2}}](\tau) dx' dy' dh_1 dh_2,$$

and taking its right derivative (and applying Lemma 2.16(a)) yields

$$-\frac{d^+}{d\tau} \mathcal{I}[S^\tau \mu_0] \geq \int_{(x', h_1) \in B_1^{R,a}} \int_{(y', h_2) \in B_2^{R,a}} \frac{d}{d\tau} I_{K_{|x'-y'|}}[\chi_{U_{x'}^{h_1}}, \chi_{U_{y'}^{h_2}}](\tau) dy' dh_2 dx' dh_1. \quad (2.27)$$

By definition of $B_1^{R,a}$ and $B_2^{R,a}$, for any $(x', h_1) \in B_1^{R,a}$ and $(y', h_2) \in B_2^{R,a}$, we can apply Lemma 2.16(b) to obtain

$$\frac{d^+}{d\tau} I_{K_{|x'-y'|}}[\chi_{U_{x'}^{h_1}}, \chi_{U_{y'}^{h_2}}](\tau) \geq \frac{1}{128} c_w a^3 \quad \text{for any } \tau \in [0, a/4], \quad (2.28)$$

where c_w is the minimum of $|K'_{|x'-y'|}(r)|$ in $[a/4, 4R]$. By definition of $K_l(r)$, we have

$$K'_{|x'-y'|}(r) = \frac{1}{2} W'(\sqrt{r^2 + |x' - y'|^2}) \frac{r}{\sqrt{r^2 + |x' - y'|^2}}.$$

Using $|x'| \leq R$ and $|y'| \leq R$ (due to definition of B_1, B_2), we have $\frac{r}{\sqrt{r^2 + |x' - y'|^2}} \leq \frac{a}{20R}$ for all $r \in [a/4, 4R]$, hence $c_w \geq \frac{a}{40R} \min_{r \in [\frac{a}{4}, 4R]} W'(r)$.

Plugging (2.28) (with the above c_w) into (2.27) finally yields

$$-\frac{d^+}{d\tau} \mathcal{I}[S^\tau \mu_0] \geq \frac{1}{6000} |B_1^{R,a}| |B_2^{R,a}| \min_{r \in [\frac{a}{4}, 4R]} W'(r) a^4 > 0 \quad \text{for all } \tau \in [0, a/4],$$

hence we can conclude the desired estimate. \square

2.2.3. Proof of Proposition 2.7. In the statement of Proposition 2.7, we assume that μ_0 is not radially decreasing up to any translation. Since Steiner symmetrization only deals with symmetrizing in one direction, we will use the following simple lemma linking radial symmetry with being symmetric decreasing about hyperplanes. Although the result is standard (see [34, Lemma 1.8]), for the sake of completeness we include here the details of the proof.

Lemma 2.17. *Let $\mu_0 \in C(\mathbb{R}^d)$. Suppose for every unit vector e , there exists a hyperplane $H \subset \mathbb{R}^d$ with normal vector e , such that μ_0 is symmetric decreasing about H . Then μ_0 must be radially decreasing up to a translation.*

Proof. For $i = 1, \dots, d$, let e_i be the unit vector with i -th coordinate 1 and all the other coordinates 0. By assumption, for each i , there exists some hyperplane H_i with normal vector e_i , such that μ_0 is symmetric decreasing about H_i . We then represent each H_i as $\{(x_1, \dots, x_d) : x_i = a_i\}$ for some $a_i \in \mathbb{R}$, and then define $a \in \mathbb{R}^d$ as $a := (a_1, \dots, a_d)$. Our goal is to prove that $\mu_0(\cdot - a)$ is radially decreasing.

We first claim that $\mu_0(x) = \mu_0(2a-x)$ for all $x \in \mathbb{R}^d$. For any hyperplane $H \subset \mathbb{R}^d$, let $T_H : \mathbb{R}^d \rightarrow \mathbb{R}^d$ be the reflection about the hyperplane H . Since μ_0 is symmetric with respect to H_1, \dots, H_d , we have $\mu_0(x) = \mu_0(T_{H_i}x)$ for $x \in \mathbb{R}^d$ and all $i = 1, \dots, d$, thus $\mu_0(x) = \mu_0(T_{H_1} \dots T_{H_d}x) = \mu_0(2a-x)$.

The claim implies that every hyperplane H passing through a must split the mass of μ_0 into half and half. Denote the normal vector of H by e . By assumption, μ_0 is symmetric decreasing about some hyperplane H' with normal vector e . The definition of symmetric decreasing implies that H' is the only hyperplane with normal vector e that splits the mass into half and half, hence H' must coincide with H . Thus μ_0 is symmetric decreasing about every hyperplane passing through a , hence we can conclude. \square

Proof of Proposition 2.7. Since μ_0 is not radially decreasing up to any translation, by Lemma 2.17, there exists some unit vector e , such that μ_0 is not symmetric decreasing about any hyperplane with normal vector e . In particular, there is a hyperplane H with normal vector e that splits the mass of μ_0 into half and half, and μ_0 is not symmetric decreasing about H . We set $e = (1, 0, \dots, 0)$ and $H = \{x_1 = 0\}$ throughout the proof without loss of generality.

Note that if we set $\mu(\tau, \cdot) = S^\tau \mu_0$, then it directly satisfies (2.14) for a short time, since $\mathcal{I}[S^\tau \mu_0]$ is decreasing at least linearly for a short time by Proposition 2.14, and we also have $\mathcal{S}[S^\tau \mu_0]$ is constant in τ . However, $S^\tau \mu_0$ does not satisfy (2.15) and (2.16). To solve this problem, we will modify $S^\tau \mu_0$ into $\tilde{S}^\tau \mu_0$, where we make the set $U_{x'}^h := \{x_1 \in \mathbb{R} : \mu_0(x_1, x') > h\}$ travels at speed $v(h)$ rather than at constant speed 1, with $v(h)$ given by

$$v(h) := \begin{cases} 1 & h \geq h_0, \\ \left(\frac{h}{h_0}\right)^{m-1} & 0 < h < h_0, \end{cases} \quad (2.29)$$

for some sufficiently small constant $h_0 > 0$ to be determined later. More precisely, we define $\mu(\tau, \cdot) = \tilde{S}^\tau \mu_0$ as

$$\tilde{S}^\tau \mu_0(x_1, x') := \int_0^\infty \chi_{M^{v(h)\tau}(U_{x'}^h)}(x_1) dh$$

with $v(h)$ as in (2.29), and our goal is to show that such $\mu(\tau, \cdot)$ satisfies (2.14), (2.15) and (2.16) for small enough τ . For an illustration on the difference between $S^\tau \mu_0$ and $\tilde{S}^\tau \mu_0$, see Figure 4.

FIGURE 4. A sketch on μ_0 (grey), $S^\tau \mu_0$ (blue) and $\tilde{S}^\tau \mu_0$ (red dashed) for a small $\tau > 0$.

Let us first prove that for any $h_0 > 0$, $\mu(\tau, \cdot)$ satisfies (2.15) and (2.16) for $\tau \in [0, \delta_1]$, where $\delta_1 = \delta_1(m, h_0, C_0) > 0$. To show (2.16), note that the assumption $|\nabla(\mu_0^{m-1})| \leq C_0$ directly leads to the following: for any $x, y \in \mathbb{R}^d$ with $\mu_0(x) \geq h > 0$ and $\mu_0(y) = 0$, we have that $|x - y| \geq h^{m-1}/C_0$. This implies that for any connected component $D_i \subset \text{supp } \mu_0$,

$$\text{dist}(\{\mu_0 > h\} \cap D_i, \partial D_i) \geq \frac{h^{m-1}}{C_0} \quad \text{for all } h > 0. \quad (2.30)$$

Now define $D_{i,x'}$ as the one-dimensional set $\{x_1 \in \mathbb{R} : (x_1, x') \in D_i\}$. The inequality (2.30) yields

$$M^{v(h)\tau}(U_{x'}^h \cap D_{i,x'}) \subset D_{i,x'} \quad \text{for all } x' \in \mathbb{R}^{d-1}, h > 0, \tau \leq \frac{h^{m-1}}{C_0 v(h)},$$

and note that for any $h > 0$, we have $h^{m-1}/(C_0 v(h)) \geq h_0^{m-1}/C_0$ by definition of $v(h)$. Using the above equation, the definition of \tilde{S}^τ and the fact that $M^{v(h)\tau}$ is measure-preserving, we have that (2.16) holds for all $\tau \leq h_0^{m-1}/C_0$.

Next we prove (2.15). Let us fix any $y = (y_1, y') \in \mathbb{R}^d$, and denote $h = \mu_0(y)$. Using $|\nabla \mu_0^{m-1}| \leq C_0$, we have that for any $\lambda > 1$,

$$\text{dist}(y_1, U_{y'}^{\lambda h}) \geq \frac{(\lambda^{m-1} - 1)h^{m-1}}{C_0}.$$

So we have $y_1 \notin M^{v(\lambda h)\tau}(U_{y'}^{\lambda h})$ for all $\tau \leq \frac{(\lambda^{m-1} - 1)h^{m-1}}{C_0 v(\lambda h)}$, which is uniformly bounded below by $\frac{(\lambda^{m-1} - 1)h_0^{m-1}}{C_0 \lambda^{m-1}}$ due to the fact that $v(\lambda h) \leq (\lambda h/h_0)^{m-1}$ for all h . By definition of \tilde{S}^τ and the fact that $\mu_0(y) = h$, the following holds for all $\lambda > 1$:

$$\tilde{S}^\tau[\mu_0](y) \leq \lambda \mu_0(y) \quad \text{for all } \tau \leq \frac{(\lambda^{m-1} - 1)h_0^{m-1}}{C_0 \lambda^{m-1}}.$$

Note that there exists $c_m^1 > 0$ only depending on m , such that $\lambda^{m-1} - 1 \geq c_m^1(\lambda - 1)$ for all $1 < \lambda < 2$. Hence for all $1 < \lambda < 2$ we have

$$\tilde{S}^\tau[\mu_0](y) - \mu_0(y) \leq (\lambda - 1)\mu_0(y) \quad \text{for } \tau = \frac{c_m^1 h_0^{m-1}}{C_0 2^{m-1}}(\lambda - 1),$$

and this directly implies

$$\tilde{S}^\tau[\mu_0](y) - \mu_0(y) \leq \frac{C_0 2^{m-1}}{c_m^1 h_0^{m-1}} \mu_0(y) \tau \quad \text{for all } \tau \leq \frac{c_m^1 h_0^{m-1}}{C_0 2^{m-1}}. \quad (2.31)$$

Similarly, for any $0 < \eta < 1$ we have $\text{dist}(y_1, (U_{y'}^{\eta h})^c) \geq \frac{(1 - \eta^{m-1})h^{m-1}}{C_0}$, and an identical argument as above gives us

$$\tilde{S}^\tau[\mu_0](y) \geq \eta \mu_0(y) \quad \text{for all } \tau \leq \frac{(1 - \eta^{m-1})h_0^{m-1}}{C_0 \eta^{m-1}}.$$

Now we let $c_m^2 > 0$ be such $1 - \eta^{m-1} \geq c_m^2(1 - \eta)$ for all $\frac{1}{2} < \eta < 1$. Hence we have $\tilde{S}^\tau[\mu_0](y) - \mu_0(y) \geq -(1 - \eta)\mu_0(y)$ for $\tau = \frac{c_m^2 h_0^{m-1}}{C_0}(1 - \eta)$, which implies

$$\tilde{S}^\tau[\mu_0](y) - \mu_0(y) \geq -\frac{C_0}{c_m^2 h_0^{m-1}} \mu_0(y) \tau \quad \text{for all } \tau \leq \frac{c_m^2 h_0^{m-1}}{2C_0}. \quad (2.32)$$

Combining (2.31) and (2.32) together, we have that for any $h_0 > 0$, (2.15) holds for some C_1 for all $\tau \in [0, \delta_1]$, where both $C_1 > 0$ and $\delta_1 > 0$ depend on C_0, h_0 and m .

Finally, we will show that (2.14) holds for $\mu(\tau) = \tilde{S}^\tau[\mu_0]$ if we choose $h_0 > 0$ to be sufficiently small. First, we point out that $\mathcal{S}[\tilde{S}^\tau \mu_0]$ is *not* preserved for all τ . This is because when different level sets are moving at different speed $v(h)$, we no longer have that $M^{v(h_1)\tau}(U_{x'}^{h_1}) \subset M^{v(h_2)\tau}(U_{x'}^{h_2})$ for all $h_1 > h_2$. Nevertheless, we claim it is still true that

$$\mathcal{S}[\tilde{S}^\tau \mu_0] \leq \mathcal{S}[\mu_0] \quad \text{for all } \tau \geq 0. \quad (2.33)$$

To see this, note that the definition of \tilde{S}^τ and the fact that $M^{v(h)\tau}$ is measure preserving give us

$$|\{\tilde{S}^\tau \mu_0 > h\}| \leq |\{\mu_0 > h\}| \quad \text{for all } h > 0, \tau \geq 0,$$

regardless of the definition of $v(h)$. This implies that $\int f(\tilde{S}^\tau \mu_0(x))dx \leq \int f(\mu_0(x))dx$ for any convex increasing function f , yielding (2.33). Indeed, using the regularity assumption $|\nabla \mu_0^{m-1}| \leq$

C_0 and the particular $v(h)$ in (2.29), one can show that $\mathcal{S}[\tilde{S}^\tau \mu_0]$ is preserved for small enough τ , but we will not pursue in this direction since (2.33) is sufficient for us.

Due to (2.33) and the fact that $\mathcal{E}[\cdot] = \mathcal{S}[\cdot] + \mathcal{I}[\cdot]$, in order to prove (2.14), it suffices to show

$$\mathcal{I}[\tilde{S}^\tau \mu_0] \leq \mathcal{I}[\mu_0] - c_0 \tau \quad \text{for } \tau \in [0, \delta_0], \text{ for some } c_0 > 0 \text{ and } \delta_0 > 0. \quad (2.34)$$

Recall that Proposition 2.14 gives that $\mathcal{I}[S^\tau \mu_0] \leq \mathcal{I}[\mu_0] - c\tau$ for $\tau \in [0, \delta]$ with some $c > 0$ and $\delta > 0$. As a result, to show (2.34), all we need is to prove that if $h_0 > 0$ is sufficiently small, then

$$\left| \mathcal{I}[\tilde{S}^\tau \mu_0] - \mathcal{I}[S^\tau \mu_0] \right| \leq \frac{c\tau}{2} \quad \text{for all } \tau. \quad (2.35)$$

To show (2.35), we first split $S^\tau \mu_0$ as the sum of two integrals in $h \in [h_0, \infty)$ and $h \in [0, h_0]$:

$$S^\tau \mu_0(x_1, x') = \int_{h_0}^{\infty} \chi_{M^\tau(U_{x'}^h)}(x_1) dh + \int_0^{h_0} \chi_{M^\tau(U_{x'}^h)}(x_1) dh =: f_1(\tau, x) + f_2(\tau, x). \quad (2.36)$$

We then split $\tilde{S}^\tau \mu_0$ similarly, and since $v(h) = 1$ for all $h > h_0$ we obtain

$$\tilde{S}^\tau \mu_0(x_1, x') = f_1(\tau, x) + \int_0^{h_0} \chi_{M^{v(h)\tau}(U_{x'}^h)}(x_1) dh =: f_1(\tau, x) + \tilde{f}_2(\tau, x). \quad (2.37)$$

For any $\tau \geq 0$, we have $\|f_1(\tau, \cdot)\|_{L^\infty(\mathbb{R}^d)} \leq \|\mu_0\|_{L^\infty(\mathbb{R}^d)}$, while $\|f_2(\tau, \cdot)\|_{L^\infty(\mathbb{R}^d)}$ and $\|\tilde{f}_2(\tau, \cdot)\|_{L^\infty(\mathbb{R}^d)}$ are both bounded by h_0 . As for the L^1 norm, we have that $\|f_1(\tau, \cdot)\|_{L^1(\mathbb{R}^d)} \leq \|\mu_0\|_{L^1(\mathbb{R}^d)}$, and

$$\|f_2(\tau, \cdot)\|_{L^1(\mathbb{R}^d)} = \|\tilde{f}_2(\tau, \cdot)\|_{L^1(\mathbb{R}^d)} = \int_{\mathbb{R}^d} \min\{\mu_0(x), h_0\} dx =: m_{\mu_0}(h_0),$$

where $m_{\mu_0}(h_0)$ approaches 0 as $h_0 \searrow 0$.

Also, since $v(h) \leq 1$, we know that for each $\tau \geq 0$, there is a transport map $\mathcal{T}(\tau, \cdot) : [0, \infty) \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ with $\sup_{x \in \mathbb{R}^d} |\mathcal{T}(\tau, x) - x| \leq 2\tau$, such that $\mathcal{T}(\tau, \cdot) \# f_2(\tau, \cdot) = \tilde{f}_2(\tau, \cdot)$ (that is, $\int \tilde{f}_2(\tau, x) \varphi(x) dx = \int f_2(\tau, x) \varphi(\mathcal{T}(\tau, x)) dx$ for any measurable function φ). Indeed, since the level sets of f_2 are traveling at speed 1 and the level sets of \tilde{f}_2 are traveling with speed $v(h)$, for each τ we can find a transport plan between them with maximal displacement L^∞ distance at most 2τ in its support. Since these densities are both in L^∞ , there is an optimal transport map for the ∞ -Wasserstein such that $|\mathcal{T}(\tau, x) - x| \leq 2\tau$, see [29].

Using the decompositions (2.36), (2.37) and the definition of $\mathcal{I}[\cdot]$, we obtain, omitting the τ dependence on the right hand side,

$$\begin{aligned} \left| \mathcal{I}[\tilde{S}^\tau \mu_0] - \mathcal{I}[S^\tau \mu_0] \right| &\leq \underbrace{\left| \int f_2(W * f_1) dx - \int \tilde{f}_2(W * f_1) dx \right|}_{=: A_1(\tau)} \\ &\quad + \frac{1}{2} \underbrace{\left| \int f_2(W * f_2) dx - \int \tilde{f}_2(W * \tilde{f}_2) dx \right|}_{=: A_2(\tau)}, \end{aligned}$$

and we will bound $A_1(\tau)$ and $A_2(\tau)$ in the following. For $A_1(\tau)$, denote $\Phi(\tau, \cdot) =: W * f_1(\tau, \cdot)$, and using the L^∞ , L^1 bounds on f_1 and the assumptions (K2), (K3), we proceed in the same way as in (2.4) to obtain that $\|\nabla \Phi\|_{L^\infty(\mathbb{R}^d)} \leq C = C(\|\mu_0\|_{L^\infty(\mathbb{R}^d)}, \|\mu_0\|_{L^1(\mathbb{R}^d)}, C_w, d)$.

Using that $\mathcal{T}(\tau, \cdot) \# f_2(\tau, \cdot) = \tilde{f}_2(\tau, \cdot)$, we can rewrite $A_1(\tau)$ as

$$\begin{aligned} A_1(\tau) &= \left| \int f_2(x) (\Phi(x) - \Phi(\mathcal{T}(\tau, x))) dx \right| \\ &\leq \|f_2(\tau)\|_{L^1(\mathbb{R}^d)} \sup_{x \in \mathbb{R}^d} |\Phi(x) - \Phi(\mathcal{T}(\tau, x))| \leq m_{\mu_0}(h_0) \|\nabla \Phi\|_{L^\infty(\mathbb{R}^d)} 2\tau \\ &\leq m_{\mu_0}(h_0) C(\|\mu_0\|_{L^\infty(\mathbb{R}^d)}, \|\mu_0\|_{L^1(\mathbb{R}^d)}, C_w, d) \tau, \end{aligned}$$

where the coefficient of τ can be made arbitrarily small by choosing h_0 sufficiently small. To control $A_2(\tau)$, we first use the identity $\int f(W * g)dx = \int g(W * f)dx$ to bound it by

$$A_2(\tau) \leq \left| \int f_2(W * f_2)dx - \int \tilde{f}_2(W * f_2)dx \right| + \left| \int f_2(W * \tilde{f}_2)dx - \int \tilde{f}_2(W * \tilde{f}_2)dx \right|,$$

and both terms can be controlled in the same way as $A_1(\tau)$, since both $\Phi_2 := W * f_2$ and $\tilde{\Phi}_2 := W * \tilde{f}_2$ satisfy the same estimate as Φ . Combining the estimates for $A_1(\tau)$ and $A_2(\tau)$, we can choose $h_0 > 0$ sufficiently small, depending on μ_0 and W , such that equation (2.35) would hold for all τ , which finishes the proof. \square

2.3. Proof of Theorem 2.2.

Proof. Towards a contradiction, assume there is a stationary state ρ_s that is not radially decreasing. Due to Lemma 2.3, we have that $\rho_s \in C(\mathbb{R}^d) \cap L_+^1(\mathbb{R}^d)$, and $|\nabla \rho_s^{m-1}| \leq C_0$ in $\text{supp } \rho_s$ for some $C_0 > 0$. This enables us to apply Proposition 2.7 to ρ_s , hence there exists a continuous family of $\mu(\tau, \cdot)$ with $\mu(0, \cdot) = \rho_s$ and constants $C_1 > 0, c_0 > 0, \delta_0 > 0$, such that the following holds for all $\tau \in [0, \delta_0]$:

$$\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s] \leq -c_0\tau, \quad (2.38)$$

$$|\mu(\tau, x) - \rho_s(x)| \leq C_1\rho_s(x)\tau \quad \text{for all } x \in \mathbb{R}^d, \quad (2.39)$$

$$\int_{D_i} \mu(\tau, x) - \rho_s(x)dx = 0 \text{ for any connected component } D_i \text{ of } \text{supp } \rho_s. \quad (2.40)$$

Next we will use (2.39) and (2.40) to directly estimate $\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s]$, and our goal is to show that there exists some $C_2 > 0$, such that

$$|\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s]| \leq C_2\tau^2 \quad \text{for } \tau \text{ sufficiently small.} \quad (2.41)$$

We then directly obtain a contradiction between (2.38) and (2.41) for sufficiently small $\tau > 0$.

Let $g(\tau, x) := \mu(\tau, x) - \rho_s(x)$. Due to (2.39), we have $|g(\tau, x)| \leq C_1\rho_s(x)\tau$ for all $x \in \mathbb{R}^d$ and $\tau \in [0, \delta_0]$. Hence $\text{supp } g(\tau) \subset \text{supp } \rho_s$ for such τ . Using the notation $g(\tau, x)$, we have the following (where in the integrand we omit the x dependence, due to space limitations)

$$\begin{aligned} \mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s] &= \int \frac{((\rho_s + g(\tau))^m - \rho_s^m)}{m-1} dx + \frac{1}{2} \int (\rho_s + g(\tau))(W * (\rho_s + g(\tau))) - \rho_s(W * \rho_s) dx \\ &= \int_{\text{supp } \rho_s} \underbrace{\frac{\rho_s^m}{m-1} \left(\left(1 + \frac{g(\tau)}{\rho_s} \right)^m - 1 \right)}_{:=T(\tau, x)} dx + \int g(\tau)(W * \rho_s) + \frac{1}{2}g(\tau)(W * g(\tau)) dx \end{aligned} \quad (2.42)$$

Recall that for all $|a| < 1/2$, we have the elementary inequality

$$|(1+a)^m - 1 - ma| \leq C(m)a^2 \text{ for some } C(m) > 0.$$

Since for all $x \in \text{supp } \rho_s$ and $\tau \leq \min\{\delta_0, C_1/2\}$ we have $|g(\tau, x)/\rho_s(x)| \leq \frac{1}{2}$, we can replace a by $g(x)/\rho_s(x)$ in the above inequality, then multiply $\frac{1}{m-1}\rho_s^m$ to both sides to obtain the following (with $C_2(m) = C(m)/(m-1)$):

$$\left| T(\tau, x) - \frac{m}{m-1}g(\tau, x)\rho_s(x)^{m-1} \right| \leq C_2(m)\rho_s^{m-2}g(\tau)^2.$$

Applying this to (2.42), we have the following for all $\tau \leq \min\{\delta_0, C_1/2\}$:

$$\begin{aligned} |\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s]| &\leq \left| \int_{\text{supp } \rho_s} g(\tau) \left(\frac{m}{m-1}\rho_s^{m-1} + W * \rho_s \right) dx \right| + \left| \frac{1}{2} \int g(\tau)(W * g(\tau)) dx \right| \\ &\quad + C_2(m) \left| \int \rho_s^{m-2}g(\tau)^2 dx \right| \\ &=: I_1 + I_2 + I_3. \end{aligned}$$

Since ρ_s is a steady state solution, from (2.8) we have $\frac{m}{m-1}\rho_s^{m-1} + W * \rho_s = C_i$ in each connected component $D_i \subset \text{supp } \rho_s$, hence $I_1 \equiv 0$ for all $\tau \in [0, \delta_0]$ due to (2.40) and the definition of $g(\tau, \cdot)$.

For I_2 and I_3 , since $|g(\tau, x)| \leq C_1 \rho_s(x) \tau$ for $\tau \in [0, \delta_0]$, we directly have

$$I_2 \leq \frac{1}{2} C_1^2 \tau^2 \int |\rho_s(W * \rho_s)| dx \leq M \tau^2,$$

$$I_3 \leq C_2(m) C_1^2 \tau^2 \int \rho_s^m dx \leq M \tau^2,$$

for some $M > 0$ depending on $\|\rho_s\|_{L^1(\mathbb{R}^d)}, \|\rho_s\|_{L^\infty(\mathbb{R}^d)}, m$ and d , and putting them together finally gives $|\mathcal{E}[\mu(\tau)] - \mathcal{E}[\rho_s]| \leq 2M \tau^2$ for all $\tau \leq \min\{\delta_0, C_1/2\}$, hence we can conclude. \square

3. EXISTENCE OF GLOBAL MINIMIZERS

In Section 2, we showed that if $\rho_s \in L_+^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$ is a stationary state of (1.1) in the sense of Definition 2.1 and it satisfies $\omega(1 + |x|)\rho_s \in L^1(\mathbb{R}^d)$, then it must be radially decreasing up to a translation. This section is concerned with the existence of such stationary solutions. Namely, under (K1)-(K4) and one of the extra assumptions (K5) or (K6) below, we will show that for any given mass, there indeed exists a stationary solution satisfying the above conditions. We will generalize the arguments of [22] to show that there exists a radially decreasing global minimizer ρ of the functional (2.5) given by

$$\mathcal{E}[\rho] = \frac{1}{m-1} \int_{\mathbb{R}^d} \rho^m dx + \frac{1}{2} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} W(x-y) \rho(x) \rho(y) dx dy$$

over the class of admissible densities

$$\mathcal{Y}_M := \left\{ \rho \in L_+^1(\mathbb{R}^d) \cap L^m(\mathbb{R}^d) : \|\rho\|_{L^1(\mathbb{R}^d)} = M, \int_{\mathbb{R}^2} x \rho(x) dx = 0, \omega(1 + |x|) \rho(x) \in L^1(\mathbb{R}^d) \right\},$$

and with the potential satisfying at least (K1)-(K4). Note that the condition on the zero center of mass has to be understood in the improper integral sense, i.e.

$$\int_{\mathbb{R}^2} x \rho(x) dx = \lim_{R \rightarrow \infty} \int_{|x| < R} x \rho(x) dx = 0$$

since we do not assume that the first moment is bounded in the class \mathcal{Y}_M . In order to avoid loss of mass at infinity, we need to assume some growth condition at infinity. In this section, we will obtain the existence of global minimizers under two different conditions related to the works [52, 4, 22], and show that such global minimizers are indeed L^1 and L^∞ stationary solutions. Namely, we assume further that the potential W satisfies at infinity either the property

$$(K5) \quad \lim_{r \rightarrow +\infty} \omega_+(r) = +\infty,$$

or

$$(K6) \quad \lim_{r \rightarrow +\infty} \omega_+(r) = \ell \in (0, +\infty) \text{ where the non-negative potential } \mathcal{K} := \ell - W \text{ is such that, in the case } m > 2, \mathcal{K} \in L^{\hat{p}}(\mathbb{R}^d \setminus B_1(0)), \text{ for some } 1 \leq \hat{p} < \infty, \text{ while for the case } 2 - (2/d) < m \leq 2 \text{ we will require that } \mathcal{K} \in L^{p,\infty}(\mathbb{R}^d \setminus B_1(0)), \text{ for some } 1 \leq p < \infty. \text{ Moreover, there exists an } \alpha \in (0, d) \text{ for which } m > 1 + \alpha/d \text{ and}$$

$$\mathcal{K}(\tau x) \geq \tau^{-\alpha} \mathcal{K}(x), \quad \forall \tau \geq 1, \text{ for a.e. } x \in \mathbb{R}^d. \quad (3.1)$$

Here, we denote by $L^{p,\infty}(\mathbb{R}^d)$ the weak- L^p or Marcinkiewicz space of index $1 < p < \infty$. In particular, the attractive Newtonian potential (which is the fundamental solution of $-\Delta$ operator in \mathbb{R}^d) is covered by these assumptions: for $d = 1, 2$ it satisfies (K5), whereas for $d \geq 3$ it satisfies (K6) with $\alpha = d - 2$.

Notice that the subadditivity-type condition (K4) allows to claim that $\mathcal{E}[\rho]$ is finite over the class \mathcal{Y}_M : indeed if we split the W into its positive part W_+ and negative part W_- as done in the bound of ψ_s in Section 2, the integral with kernel W_- is finite by the HLS inequality, see (3.2) below, while by (K4) we infer

$$\begin{aligned} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} W_+(x-y) \rho(x) \rho(y) dx dy &= \int_{\mathbb{R}^d} \int_{|x-y| \geq 1} \omega_+(|x-y|) \rho(x) \rho(y) dx dy \\ &\leq CM^2 + 2M \int_{\mathbb{R}^d} \omega(1+|x|) \rho(x) dx. \end{aligned}$$

3.1. Minimization of the Free Energy functional. The existence of minimizers of the functional \mathcal{E} can be proven with different arguments according to the choice between condition (K5) or (K6): indeed, (K5) produces a quantitative version of the mass confinement effect while (K6) does it in a nonconstructive way. For such a difference, we first briefly discuss the case when condition (K6) is employed, as it can be proven by a simple application of Lion's concentration-compactness principle [52] and its variant in [4].

Theorem 3.1. *Assume that conditions (K1)-(K4) and (K6) hold. Then for any positive mass M , there exists a global minimizer ρ_0 , which is radially symmetric and decreasing, of the free energy functional \mathcal{E} in \mathcal{Y}_M . Moreover, all global minimizers are radially symmetric and decreasing.*

Proof. We write $\mathcal{E}[\rho] = \tilde{\mathcal{E}}[\rho] + \frac{\ell}{2}M^2$, where

$$\tilde{\mathcal{E}}[\rho] = \frac{1}{m-1} \int_{\mathbb{R}^d} \rho^m dx - \frac{1}{2} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \mathcal{K}(x-y) \rho(x) \rho(y) dx dy,$$

being the kernel \mathcal{K} nonnegative and radially decreasing; furthermore condition (K3) implies $\mathcal{K} \in L^{p,\infty}(B_1(0))$, where $p = d/(d-2)$. Then we are in position to apply [4, Theorem 1] for $m > 2$ and [52, Corollary II.1] for $2 - (2/d) < m \leq 2$ to get the existence of a radially decreasing minimizer $\rho_0 \in \mathcal{Y}_M$ of $\tilde{\mathcal{E}}$ (and then of \mathcal{E}). Moreover, since \mathcal{K} is strictly radially decreasing, all global minimizers are radially decreasing. \square

When considering the presence of condition (K5) a direct control of the mass confinement phenomenon is possible and the concentration-compactness principle is not applicable. Then we first prove the following Lemma, which provides a reversed Riesz inequality, allowing to reduce the study the minimization of \mathcal{E} to the set of all the radially decreasing density in \mathcal{Y}_M .

Lemma 3.2. *Assume that conditions (K1)-(K5) hold and take a density ρ such that*

$$\rho \in L^1_+(\mathbb{R}^d), \quad \omega(1+|x|) \rho(x) \in L^1(\mathbb{R}^d).$$

Then the following inequality holds:

$$\mathcal{I}[\rho] = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} W(x-y) \rho(x) \rho(y) dx dy \geq \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} W(x-y) \rho^\#(x) \rho^\#(y) dx dy = \mathcal{I}[\rho^\#]$$

and the equality occurs only if and only if ρ is a translate of $\rho^\#$.

Proof. The proof proceeds exactly as in [21, Lemma 2], up to replacing the function $k(r)$ defined there by the function

$$\kappa(r) = \begin{cases} -\omega(r) & \text{if } r \leq r_0 \\ -\omega(r_0) - \int_{r_0}^r \omega'(s) \frac{1+r_0^2}{1+s^2} ds & \text{if } r > r_0, \end{cases}$$

being $r_0 > 0$ fixed. \square

Theorem 3.3. *Assume that (K1)-(K5) hold, then the conclusions of Theorem 3.1 remain true.*

Proof. We follow the main lines of [22, Theorem 2.1]. By Lemma 3.2 we can restrict ourselves to consider only radially decreasing densities ρ . In order to show that $\mathcal{I}[\rho]$ is bounded from below, we first argue in the case $d \geq 3$. Thanks to conditions (K1)-(K2) we have

$$\int_{\mathbb{R}^d} \int_{\mathbb{R}^d} W(x-y) \rho(x) \rho(y) dx dy \geq -C \int_{\mathbb{R}^d} \int_{|x-y| \leq 1} \frac{\rho(x) \rho(y)}{|x-y|^{d-2}} dx dy \geq -C \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{\rho(x) \rho(y)}{|x-y|^{d-2}} dx dy.$$

Now we observe that

$$1 < \frac{2d}{d+2} < m$$

and $\frac{d-2}{d} + \frac{d+2}{2d} + \frac{d+2}{2d} = 2$, then by the classical HLS and L^p interpolation inequalities, we find

$$\mathcal{I}[\rho] = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} W(x-y) \rho(x) \rho(y) dx dy \geq -C \|\rho\|_{L^{2d/(d+2)}(\mathbb{R}^d)}^2 \geq -C \|\rho\|_{L^1(\mathbb{R}^d)}^{2\alpha} \|\rho\|_{L^m(\mathbb{R}^d)}^{2(1-\alpha)}, \quad (3.2)$$

where $\alpha = \frac{1}{m-1} (m \frac{d+2}{2d} - 1)$. Then by (3.2) we find that

$$\mathcal{E}[\rho] \geq \frac{1}{m-1} \|\rho\|_{L^m(\mathbb{R}^d)}^m - CM^{2\alpha} \|\rho\|_{L^m(\mathbb{R}^d)}^{2(1-\alpha)} \quad (3.3)$$

where we notice that $m > 2(1-\alpha)$ if and only if $m > 2 - \frac{2}{d}$, which is the diffusion dominated regime we work with. Then by (3.3) we can find a constant $C_1 > 0$ and a sufficiently large constant C_2 such that

$$\mathcal{E}[\rho] \geq -C_1 + C_2 \|\rho\|_{L^m(\mathbb{R}^d)}^m.$$

Concerning the case $d = 2$, we observe that conditions (K1)-(K2) yields

$$\begin{aligned} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} W(x-y) \rho(x) \rho(y) dx dy &\geq -C \int_{\mathbb{R}^2} dx \int_{|x-y| \leq 1} \log(|x-y|) \rho(x) \rho(y) dx dy \\ &\geq -C \int_{\mathbb{R}^2} dx \int_{\mathbb{R}^2} \log(|x-y|) \rho(x) \rho(y) dx dy \end{aligned}$$

and we can use the classical log-HLS inequality and the arguments of [22] to conclude.

Concerning the mass confinement, due to (K5) and the same arguments in [22], see also Lemma 4.16, allow us to show

$$\int_{|x| > R} \rho(x) dx \leq \frac{C}{\omega(R)} \xrightarrow{R \rightarrow \infty} 0.$$

Finally, we should check that the interaction potential W is lower semicontinuous as shown in [22, page8]. Indeed, the only technical point to verify in this more general setting relates to the control of the truncated interaction potential A^ε for $d \geq 3$. Notice that we can estimate due to (2.3)

$$\begin{aligned} |A^\varepsilon[\rho]| &:= \left| \int_{\mathbb{R}^d} \int_{|x-y| \leq \varepsilon} W(x-y) \rho(x) \rho(y) dx dy \right| \leq C \int_{\mathbb{R}^d} \int_{|x-y| \leq \varepsilon} \frac{\rho(x) \rho(y)}{|x-y|^{d-2}} dx dy \\ &= C \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \rho(x) (\chi_{B_\varepsilon(0)} \mathcal{N})(x-y) \rho(y) dx dy. \end{aligned}$$

Now recall that the Newtonian potential

$$\Psi_\rho(x) = \int_{\mathbb{R}^d} \frac{\rho(y)}{|x-y|^{d-2}} dy$$

is well defined for a.e. $x \in \mathbb{R}^d$ and is in $L_{loc}^1(\mathbb{R}^d)$, see [33, Theorem 2.21], then for a.e. $x \in \mathbb{R}^d$ we have $\chi_{B_\varepsilon(0)} \mathcal{N} * \rho \rightarrow 0$ as $\varepsilon \rightarrow 0$. Moreover, by the HLS inequality we have

$$\rho(x) (\chi_{B_\varepsilon(0)} \mathcal{N} * \rho)(x) \leq \rho(x) \Psi_\rho(x) \in L_{loc}^1(\mathbb{R}^d)$$

with

$$\|\rho(x) \Psi_\rho\|_{L^1(\mathbb{R}^d)} \leq C \|\rho\|_{L^1(\mathbb{R}^d)}^{2\alpha} \|\rho\|_{L^m(\mathbb{R}^d)}^{2(1-\alpha)}.$$

Then Lebesgue's dominated convergence theorem allows to conclude that $A^\varepsilon[\rho] \rightarrow 0$ as $\varepsilon \rightarrow 0$. This convergence is uniform taken on a minimizing sequence ρ_n .

Now, all ingredients are there to argue as in [22] showing that \mathcal{E} achieves its infimum in the class of all radially decreasing densities in \mathcal{Y}_M . \square

A useful result, which will be used in the next arguments, regards the behavior at infinity of the so called W -potential, namely the function

$$\psi_f(x) = \int_{\mathbb{R}^d} W(x-y)f(y)dy.$$

Following the blueprint of [28, Lemma 1.1], we have the following result.

Lemma 3.4. *Assume that (K1)-(K5) hold, and let*

$$f \in L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d \setminus B_1(0)), \omega(1+|x|)f(x) \in L^1(\mathbb{R}^d).$$

Then

$$\frac{\psi_f(x)}{W(x)} \rightarrow \int_{\mathbb{R}^d} f(y)dy \quad \text{as } |x| \rightarrow +\infty.$$

Proof. As in Chae-Tarantello [28], we first set

$$\sigma(x) := \frac{\psi_f(x)}{\omega(|x|)} - \int_{\mathbb{R}^d} f(y)dy = \frac{1}{\omega(|x|)} \int_{\mathbb{R}^d} [\omega(|x-y|) - \omega(|x|)] f(y)dy \quad (3.4)$$

so that our aim will be to show that $\sigma(x) \rightarrow 0$ as $|x| \rightarrow \infty$. Assume that $|x| > 2$. We then write

$$\sigma(x) = \sigma_1(x) + \sigma_2(x) + \sigma_3(x),$$

where σ_i , $i = 1, 2, 3$, are defined by breaking the integral on the right hand side of (3.4) into:

$$D_1 = \{y : |x-y| < 1\}, D_2 = \{y : |x-y| > 1, |y| \leq R\} \text{ and } D_3 = \{y : |x-y| > 1, |y| > R\}$$

respectively, where $R > 2$ is a fixed constant. Recall that (K2) implies $|\omega(r)| \leq C\phi(r)$ for $r \leq 1$, with ϕ given in (2.3). Thus, we have

$$\begin{aligned} |\sigma_1(x)| &\leq \frac{1}{\omega(|x|)} \int_{|x-y| < 1} |\omega(|x-y|) - \omega(|x|)| |f(y)| dy \\ &\leq \frac{C}{\omega(|x|)} \int_{|x-y| < 1} \phi(|x-y|) |f(y)| dy + \int_{|y| > |x|-1} |f| dy \\ &\leq \frac{C\|f\|_{L^\infty(\mathbb{R}^d \setminus B_1(0))} \|\phi\|_{L^1(B_1(0))}}{\omega(|x|)} + \int_{|y| > |x|-1} |f| dy, \end{aligned}$$

where we used $f \in L^\infty(\mathbb{R}^d \setminus B_1(0))$ and $|x| > 2$ in the last inequality. This means that $\sigma_1(x) \rightarrow 0$ as $|x| \rightarrow \infty$. Moreover, we notice that

$$|\sigma_2(x)| \leq \frac{1}{\omega(|x|)} \int_{\{y \in \mathbb{R}^d : |x-y| > 1, |y| < R\}} |\omega(|x-y|) - \omega(|x|)| |f(y)| dy.$$

Since by property (K3) we can estimate in the region D_2

$$|\omega(|x-y|) - \omega(|x|)| \leq C||x-y| - |x|| \leq C|y| \leq CR,$$

such that

$$|\sigma_2(x)| \leq C \frac{R}{\omega(|x|)} \|f\|_{L^1(\mathbb{R}^d)},$$

which implies that also $\sigma_2(x) \rightarrow 0$ as $|x| \rightarrow +\infty$. As for σ_3 , for x such that $|x| > R$, using (K4)-(K5) we write

$$\begin{aligned} |\sigma_3(x)| &\leq \frac{1}{\omega(|x|)} \int_{\{y \in \mathbb{R}^d : |x-y| > 1, R < |y| < |x|\}} |\omega(|x-y|) - \omega(|x|)| |f(y)| dy \\ &\quad + \frac{1}{\omega(|x|)} \int_{\{y \in \mathbb{R}^d : |x-y| > 1, |y| > |x|\}} \omega(|x-y|) |f(y)| dy + \int_{|y| > R} |f(y)| dy \\ &\leq \frac{\omega(2|x|)}{\omega(|x|)} \int_{|y| > R} |f(y)| dy + 2 \int_{|y| > R} |f(y)| dy \\ &\quad + \frac{C_w}{\omega(|x|)} \int_{\{y \in \mathbb{R}^d : |x-y| > 1, |y| > |x|\}} [1 + \omega(1 + |x|) + \omega(1 + |y|)] |f(y)| dy \\ &\leq C \left(1 + \frac{1}{\omega(|x|)} \right) \int_{|y| > R} |f(y)| dy + \frac{1}{\omega(|x|)} \int_{\mathbb{R}^d} \omega(1 + |y|) |f(y)| dy \\ &\rightarrow C \int_{|y| > R} |f(y)| dy \end{aligned}$$

as $|x| \rightarrow +\infty$, for any fixed $R > 1$. Hence letting $R \rightarrow +\infty$ we get $\sigma_3(x) \rightarrow 0$. \square

In case of assumption (K6), we prove the following lemma, weaker than Lemma 3.7, but enough for our purposes.

Lemma 3.5. *Assume (K1)-(K4) and (K6) hold, and let $\mathcal{K} := \ell - W$ be as defined in (K6). Then the following holds for any radially decreasing $f \in L_+^1(\mathbb{R}^d)$:*

$$\lim_{|x| \rightarrow \infty} \int_{\mathbb{R}^d} \mathcal{K}(x-y) f(y) dy = 0, \quad (3.5)$$

and

$$\int_{\mathbb{R}^d} \mathcal{K}(x-y) f(y) dy \geq c \mathcal{K}(x) \text{ for all } |x| > 1, \quad (3.6)$$

where $c := 2^{-\alpha} \int_{B_1(0)} f(y) dy > 0$, with $\alpha > 0$ as given in (K6).

Proof. Since both f and \mathcal{K} are radially symmetric, we define $\bar{f}, \bar{\mathcal{K}} : [0, +\infty) \rightarrow \mathbb{R}$ such that $\bar{f}(|x|) = f(x)$, $\bar{\mathcal{K}}(|x|) = \mathcal{K}(x)$. Note that $\lim_{r \rightarrow \infty} \bar{f}(r) = \lim_{r \rightarrow \infty} \bar{\mathcal{K}}(r) = 0$ due to (K1), (K6) and the assumption on f . To prove (3.5), we break $\int_{\mathbb{R}^d} \mathcal{K}(x-y) f(y) dy$ into the following three parts with $|x| > 1$ and control them respectively by:

$$\begin{aligned} \int_{|y| > \frac{|x|}{2}, |x-y| \leq 1} \mathcal{K}(x-y) f(y) dy &\leq \|\mathcal{K}\|_{L^1(B_1(0))} \bar{f}(|x| - 1), \\ \int_{|y| > \frac{|x|}{2}, |x-y| > 1} \mathcal{K}(x-y) f(y) dy &\leq \bar{\mathcal{K}}(1) \int_{|y| > \frac{|x|}{2}} f(y) dy, \end{aligned}$$

and

$$\int_{|y| \leq \frac{|x|}{2}} \mathcal{K}(x-y) f(y) dy \leq \bar{\mathcal{K}}\left(\frac{|x|}{2}\right) \|f\|_{L^1}.$$

Since all the three parts tend to 0 as $|x| \rightarrow \infty$, we obtain (3.5). To show (3.6), we use $\mathcal{K}, f \geq 0$ to estimate

$$\begin{aligned} \int_{\mathbb{R}^d} \mathcal{K}(x-y) f(y) dy &\geq \int_{|y| \leq 1} \mathcal{K}(x-y) f(y) dy \geq \bar{\mathcal{K}}(|x| + 1) \int_{B_1(0)} f(y) dy \\ &\geq \left(\frac{|x| + 1}{|x|} \right)^{-\alpha} \bar{\mathcal{K}}(|x|) \int_{B_1(0)} f(y) dy \geq c \mathcal{K}(x) \quad \text{for any } |x| > 1, \end{aligned}$$

where we apply (K6) to obtain the third inequality, and in the last inequality we define $c := 2^{-\alpha} \int_{B_1(0)} f(y) dy > 0$. \square

Using similar arguments as in [22], we are able to derive the following result, which indeed gives a natural form of the Euler-Lagrange equation associated to the functional \mathcal{E} :

Theorem 3.6. *Assume that (K1)-(K4) and either (K5) or (K6) hold. Let $\rho_0 \in \mathcal{Y}_M$ be a global minimizer of the free energy functional \mathcal{E} . Then for some positive constant $D[\rho_0]$, we have that ρ_0 satisfies*

$$\frac{m}{m-1}\rho_0^{m-1} + W * \rho_0 = D[\rho_0] \quad \text{a.e. in } \text{supp}(\rho_0) \quad (3.7)$$

and

$$\frac{m}{m-1}\rho_0^{m-1} + W * \rho_0 \geq D[\rho_0] \quad \text{a.e. outside } \text{supp}(\rho_0)$$

where

$$D[\rho_0] = \frac{2}{M}G[\rho_0] + \frac{m-2}{M(m-1)}\|\rho_0\|_{L^m(\mathbb{R}^d)}^m.$$

As a consequence, any global minimizer of \mathcal{E} verifies

$$\frac{m}{m-1}\rho_0^{m-1} = (D[\rho_0] - W * \rho_0)_+. \quad (3.8)$$

We now turn to show compactness of support and boundedness of the minimizers.

Lemma 3.7. *Assume that (K1)-(K4) and either (K5) or (K6) hold and let $\rho_0 \in \mathcal{Y}_M$ be a global minimizer of the free energy functional \mathcal{E} . Then ρ_0 is compactly supported.*

Proof. By Theorems 3.1 and 3.3, ρ_0 is radially decreasing under either set of assumptions. In addition, under the assumption (K5), Lemma 3.4 gives that

$$\frac{(W * \rho_0)(x)}{W(x)} \rightarrow \|\rho\|_{L^1(\mathbb{R}^d)} \quad \text{as } |x| \rightarrow \infty,$$

hence combining this with (K5) gives us $(W * \rho_0)(x) \rightarrow +\infty$ as $|x| \rightarrow \infty$. It implies that the right hand side of (3.8) must have compact support, hence ρ_0 must have compact support too.

Under the assumption (K6), towards a contradiction, suppose ρ_0 does not have compact support. Then ρ_0 must be strictly positive in \mathbb{R}^d since it is radially decreasing. We can then write (3.7) as

$$\frac{m}{m-1}\rho_0^{m-1} - \mathcal{K} * \rho_0 = C \quad \text{a.e. in } \mathbb{R}^d$$

for some $C \in \mathbb{R}$, where $\mathcal{K} := \ell - W$ is as given in (K6). Indeed, C must be equal to 0, since both $\rho_0(x)$ and $(\mathcal{K} * \rho_0)(x)$ tend to 0 as $|x| \rightarrow \infty$, where we used (3.5) on the latter convergence. Thus

$$\rho_0(x) = \left(\frac{m-1}{m}(\mathcal{K} * \rho_0)(x) \right)^{\frac{1}{m-1}} \geq \left(\frac{m-1}{m}c\mathcal{K}(x) \right)^{1/(m-1)} \quad \text{for a.e. } |x| > 1, \quad (3.9)$$

where we applied (3.6) to obtain the last inequality, with $c := 2^{-\alpha} \int_{B_1(0)} \rho_0(y) dy > 0$. Due to the assumptions (3.1) and $\alpha < \frac{m-1}{d}$ in (K6), we have $\int_{|x|>1} \mathcal{K}(x)^{1/(m-1)} dx = +\infty$. Combining this with (3.9) leads to $\rho_0 \notin L^1(\mathbb{R}^d)$, a contradiction. \square

Lemma 3.8. *Assume that (K1)-(K4) and either (K5) or (K6) hold and let $\rho_0 \in \mathcal{Y}_M$ be a global minimizer of the free energy functional \mathcal{E} . Then $\rho_0 \in L^\infty(\mathbb{R}^d)$.*

Proof. By Theorem 3.1, Theorem 3.3 and Lemma 3.7, ρ_0 is radially decreasing and has compact support say inside the ball $B_R(0)$. Let us first concentrate on the proof under assumption (K5). For notational simplicity in this proof, we will denote by $\|\rho_0\|_m$ the $L^m(\mathbb{R}^d)$ -norm of ρ_0 .

We will show that $\rho_0 \in L^\infty(\mathbb{R}^d)$ by different arguments in several cases:

Case A: $d \leq 2$. Since ρ_0 is supported in $B_R(0)$, we can then find some C_w^1 and C_w^2 , such that $W \geq -C_w^1 \mathcal{N} - C_w^2$ in $B_{2R}(0)$. Hence for any $r < R$, we have

$$-(\rho_0 * W)(r) \leq -(\rho_0 * (-C_w^1 \mathcal{N} - C_w^2))(r) \leq C_w^1(\rho_0 * \mathcal{N})(r) + C_w^2 \|\rho_0\|_1,$$

thus recalling (2.4)

$$(\rho_0 * W^-)(r) \leq C_w^1(\rho_0 * \mathcal{N})(r) + C_w^2\|\rho_0\|_1 + (\rho_0 * W^+)(r) \leq C_w^1(\rho_0 * \mathcal{N})(r) + C_w^2\|\rho_0\|_1 + \tilde{C}.$$

Then by equation (3.8) it will be enough to show that the *Newtonian potential* $\rho_0 * \mathcal{N}$ is bounded in $B_R(0)$ for $d = 1, 2$. In $d = 1$, this is trivial. In $d = 2$ it follows from [36, Lemma 9.9] since we have that $\rho_0 * \mathcal{N} \in \mathcal{W}^{2,m}(B_R(0))$, then Morrey's Theorem yields $\rho_0 * \mathcal{N} \in L^\infty(B_R(0))$.

Case B: $d \geq 3$ and $m > d/2$. In this case we get $W^- \leq C_w \mathcal{N}$ in the whole \mathbb{R}^d for some constant C_w , so we have for $r > 0$

$$(\rho_0 * W^-)(r) \leq C_w(\rho_0 * \mathcal{N})(r).$$

Then using Sobolev's embedding theorem again, we easily argue that for $m > d/2$ we find $(\rho_0 * W^-)(r) \in L_{loc}^\infty(\mathbb{R}^d)$, hence $\rho_0 \in L^\infty(\mathbb{R}^d)$ by (3.8) again.

Case C: $d \geq 3$ and $2 - \frac{2}{d} < m \leq d/2$. We aim to prove that $\rho_0(0)$ is finite which is sufficient for the boundedness of ρ_0 since ρ_0 is radially decreasing. This is done by an inductive argument. To begin with, note that we have $\|\rho_0\|_m < \infty$ by the proof of Lemma 3.2. Combining this with the fact that ρ_0 is radially decreasing, we have that $\rho_0(r)^m |B(0, r)| \leq \|\rho_0\|_m^m < \infty$, which leads to the basis step of our induction

$$\rho_0(r) \leq C(d, m, \|\rho_0\|_m) r^{-d/m} \text{ for all } r > 0.$$

We set our first exponent $\tilde{p} = -d/m$. For the induction step, we claim that if $\rho_0(r) \leq C_1(1 + r^p)$ with $-d < p < 0$, then it leads to the refined estimate

$$\rho_0(r) \leq \begin{cases} C_2(1 + r^{\frac{p+2}{m-1}}) & \text{if } p \neq -2 \\ C_2(1 + |\log r|^{\frac{1}{m-1}}) & \text{if } p = -2, \end{cases} \quad (3.10)$$

where C_2 depends on d, m, ρ_0, W and C_1 .

Indeed, taking into account (K2) and (K5), the compact support of ρ_0 together with the fact that $\mathcal{N} > 0$ for $d \geq 3$, we deduce that $W \geq -C_{w,d} \mathcal{N}$ for some constant depending on W and d . As a result, we have, for $r \in (0, 1)$,

$$-(\rho_0 * W)(r) \leq C_{w,d}(\rho_0 * \mathcal{N})(r) = C_{w,d} \left((\rho_0 * \mathcal{N})(1) - \int_r^1 \partial_r(\rho_0 * \mathcal{N})(s) ds \right). \quad (3.11)$$

We can easily bound $(\rho_0 * \mathcal{N})(1)$ by some $C(d, \|\rho_0\|_m)$. To control $\int_r^1 \partial_r(\rho_0 * \mathcal{N})(s) ds$, recall that

$$-\partial_r(\rho_0 * \mathcal{N})(s) = \frac{M(s)}{|\partial B(0, s)|} = \frac{M(s)}{\sigma_d s^{d-1}}, \quad (3.12)$$

where $M(s)$ is the mass of ρ_0 in $B(0, s)$. By our induction assumption, we have

$$M(s) \leq \int_0^s C_1(1 + t^p) \sigma_d t^{d-1} dt = C_1 \sigma_d \left(\frac{s^d}{d} + \frac{s^{d+p}}{d+p} \right).$$

Combining this with (3.12), we have

$$-\partial_r(\rho_0 * \mathcal{N})(s) \leq C_1 \left(\frac{s}{d} + \frac{s^{1+p}}{d+p} \right),$$

so we get, for $p \neq -2$,

$$-\int_r^1 \partial_r(\rho_0 * \mathcal{N})(s) ds \leq C_1 \left[\frac{1}{2d}(1 - r^2) + \frac{1}{(d+p)(2+p)}(1 - r^{2+p}) \right].$$

Plugging it into the right hand side of (3.11) yields

$$-(\rho_0 * W)(r) \leq C(d, m, \|\rho_0\|_m, C_{w,d}, C_1)(1 + r^{2+p}),$$

and using this inequality in the Euler-Lagrange Equation (3.8) leads to (3.10). Moreover, in the case $p = -2$, we have instead the inequality

$$-\int_r^1 \partial_r(\rho_0 * \mathcal{N})(s) ds \leq C_1 \left[\frac{1}{2d}(1-r^2) - \frac{1}{d-2} \log r \right].$$

Now we are ready to apply the induction starting at $\tilde{p} = -d/m$ to show $\rho_0(0) < \infty$. We will show that after a finite number of iterations our induction arrives to

$$\rho_0(r) \leq C(1+r^a) \quad (3.13)$$

for some $a > 0$, which then implies that $\rho_0(0) < \infty$. Let $g(p) := \frac{p+2}{m-1}$, which is a linear function of p with positive slope, and let us denote $g^{(n)}(p) =: \underbrace{(g \circ g \cdots \circ g)}_{n \text{ iterations}}(p)$.

Subcase C.1: $m = d/2$.- In this case, we have $\tilde{p} = -2$ and by (3.10) we obtain

$$\rho_0(r) \leq C_2(1 + |\log r|^{\frac{1}{m-1}}) \leq C_2(1 + r^{-1})$$

hence applying the first inequality in (3.10) for $p = -1$ gives us (3.13) with $a = 1/(m-1)$.

Then it remains to consider the case $m < d/2$. Notice that $-d < \tilde{p} < -2$. By (3.10) we get, for all $r \in (0, 1)$,

$$\rho_0(r) \leq C_2(1 + r^{g(\tilde{p})}). \quad (3.14)$$

Then we must consider three cases. We point out that in all the cases we need to discuss the possibility of $g^{(n)}(p) = -2$ for some n : if this happens, the logarithmic case occurs again and the result follows in a final iteration step as in Subcase C.1.

Subcase C.2: $m = 2$ and $m < d/2$.- In this case, we have $g(p) = p + 2$, hence $g^{(n)}(p) = p + 2n$, then $g^{(n)}(p) > p$ for all $n \in \mathbb{N}$ and

$$\lim_{n \rightarrow \infty} g^{(n)}(p) = +\infty.$$

Therefore we have $g^{(n)}(\tilde{p}) > 0$ for some finite n , whence iterating (3.14) n times we find $\rho_0(0) < \infty$.

Subcase C.3: $m > 2$ and $m < d/2$.- In this case, $p = 2/(m-2)$ is the only fixed point for the linear function $g(p)$. For all $p < \frac{2}{m-2}$ we have $g(p) > p$ which implies $g^{(n)}(p) > p$ for all $n \in \mathbb{N}$. Notice that

$$g^{(n)}(p) = \frac{2}{m-2} + \frac{p(m-2)-2}{(m-2)(m-1)^n}, \quad (3.15)$$

so the point $p = 2/(m-2)$ is attracting in the sense that

$$\lim_{n \rightarrow \infty} g^{(n)}(p) = \frac{2}{m-2},$$

and the convergence is uniform with respect to p . Since $\frac{2}{m-2} > 0$, it again implies that $g^{(n)}(p) > 0$ for some finite n . Then choosing $p = \tilde{p}$, we have $g^{(n)}(\tilde{p}) > 0$ for some n , then (3.14) implies $\rho_0(0) < \infty$ again.

Subcase C.4: $m < \min(2, d/2)$.- In this case, the only fixed point $\frac{2}{m-2}$ is unstable, and we have $g(p) > p$ for any $p > \frac{2}{m-2}$, then by (3.15)

$$\lim_{n \rightarrow \infty} g^{(n)}(p) = +\infty \text{ for any } p > \frac{2}{m-2}.$$

Indeed, we have $\tilde{p} > -d > \frac{2}{m-2}$, where in the last step we used $m > 2 - \frac{2}{d}$ as well as $1 < m < 2$. Hence we again obtain $g^{(n)}(\tilde{p}) > 0$ for some finite n , which finishes the last case.

Let us finally turn back to the proof if we assume (K6) instead of (K5). Notice first that the proof of the Case C can also be done as soon as the potential W satisfies the bound $W \geq -C_{w,d}(1 + \mathcal{N})$

for some $C_{w,d} > 0$. This is trivially true regardless of the dimension if the potential satisfies (K6) instead of (K5). \square

Finally, it is interesting to derive some *regularity* properties of a minimizer ρ_0 , as in [22]. Since W may not be the classical Newtonian kernel, we are led to prove a nice regularity for the W -potential $\psi_{\rho_0}(x)$ which can be transferred to ρ_0 via equation (3.7) in the support of ρ_0 . Note that (3.8) ensures that ρ_0 satisfies equation (2.1) in the sense of distributions and, as shown in (2.2)-(2.4), we find that $\psi_{\rho_0} \in \mathcal{W}_{loc}^{1,\infty}(\mathbb{R}^d)$, and thus using the regularity arguments of the proof of Lemma 2.3 again together with the compact support property, we finally have $\rho_0 \in C^{0,\alpha}(\mathbb{R}^d)$ with $\alpha = 1/(m-1)$.

We can summarize all the results in this section in the following theorem.

Theorem 3.9. *Assume that conditions (K1)-(K4) and either (K5) or (K6) hold. Then for any positive mass M , there exists a global minimizer ρ_0 of the free energy functional \mathcal{E} (2.5) defined in \mathcal{Y}_M , which is radially symmetric, decreasing, compactly supported, Hölder continuous, and a stationary solution of (1.1) in the sense of Definition 2.1.*

Putting together the previous theorem with the uniqueness of radial stationary solutions for the attractive Newtonian potential proved in [46, 22], we obtain the following result.

Corollary 3.10. *In the particular case of the attractive Newtonian potential $W(x) = -\mathcal{N}(x)$, the global minimizer obtained in Theorem 3.9 is unique among all stationary solutions in the sense of Definition 2.1.*

4. LONG-TIME ASYMPTOTICS

We now consider the particular case of (1.1) given by the Keller Segel model in two dimensions with nonlinear diffusion as

$$\partial_t \rho = \Delta \rho^m - \nabla \cdot (\rho \nabla \mathcal{N} * \rho), \quad (4.1)$$

where $m > 1$ and the logarithmic interaction kernel is defined as

$$\mathcal{N}(x) = -\frac{1}{2\pi} \log |x|.$$

This system is also referred to as the parabolic-elliptic Keller-Segel system with nonlinear diffusion, since the attracting potential $c = \mathcal{N} * \rho$ solves the Poisson equation $-\Delta c = \rho$. It corresponds exactly to the range of diffusion dominated cases as discussed in [19] since solutions do not show blow-up and are globally bounded. We will show based on the uniqueness part in Section 2 that not only the solutions to (4.1) exist globally and are uniformly bounded in time in L^∞ , but also the solutions achieve stabilization in time towards the unique stationary state for any given initial mass.

The main tool for analyzing stationary states and the existence of solutions to the evolutionary problem is again the following free energy functional

$$\mathcal{E}[\rho](t) = \int_{\mathbb{R}^2} \frac{\rho^m}{m-1} dx + \frac{1}{4\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \ln |x-y| \rho(x) \rho(y) dx dy. \quad (4.2)$$

A simple differentiation formally shows that \mathcal{E} is decaying in time along the evolution corresponding to (4.1), namely

$$\frac{d}{dt} \mathcal{E}[\rho](t) = -\mathcal{D}[\rho](t)$$

which gives rise to the following (free) energy - energy dissipation inequality for weak solutions

$$\mathcal{E}[\rho](t) + \int_0^t \mathcal{D}[\rho] d\tau \leq \mathcal{E}[\rho_0] \quad (4.3)$$

for nonnegative initial data $\rho_0(x) \in L^1((1 + \ln(1 + |x|^2))dx) \cap L^m(\mathbb{R}^2)$. The entropy dissipation is given by

$$\mathcal{D}[\rho] = \int_{\mathbb{R}^2} \rho |\nabla h[\rho]|^2 dx,$$

where here and in the following we use the notation

$$h[\rho] = \frac{m}{m-1} \rho^{m-1} - \mathcal{N} * \rho.$$

We shall note that h corresponds to $\frac{\delta \mathcal{E}}{\delta \rho}$ and that in particular the evolutionary equation (4.1) can be stated as $\partial_t \rho = \nabla \cdot (\rho \nabla h[\rho])$. Thus, this equation bears the structure of being a gradient flow of the free energy functional in the sense of probability measures, see [2, 8, 10, 26] and the references therein.

We first prove the global well-posedness of weak solutions satisfying the energy inequality (4.3) in the next subsection as well as global uniform in time estimates for the solutions. In the second subsection, we used the uniform in time estimates together with the uniqueness of the stationary states proved in Section 2 to derive the main result of this section regarding long time asymptotics for (4.1).

4.1. Global well-posedness of the Cauchy problem. In this section we analyze the existence and uniqueness of a bounded global weak solution for initial data in $L^1_{log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, where here and in the following we denote

$$L^1_{log}(\mathbb{R}^2) = L^1((1 + \ln(1 + |x|^2))dx).$$

Assuming to have a sufficiently regular solution with the gradient of the chemotactic potential being uniformly bounded, Kowalczyk [48] derived a priori bounds in L^∞ with respect to space and time for the Keller-Segel model with nonlinear diffusion on bounded domains. These a priori estimates have been improved and extended to the whole space by Calvez and Carrillo in [19]. We shall demonstrate here how these a priori estimates of [19] can be made rigorous when starting from an appropriately regularized equation leading to the following theorem.

Theorem 4.1 (Properties of weak solutions). *For any nonnegative initial data $\rho_0 \in L^1_{log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, there exists a unique global weak solution ρ to (4.1), which satisfies the energy inequality (4.3) with the energy being bounded from above and below in the sense that*

$$\mathcal{E}_* \leq \mathcal{E}[\rho](t) \leq \mathcal{E}[\rho_0]$$

for some (negative) constant \mathcal{E}_* . In particular ρ is uniformly bounded in space and time

$$\sup_{t \geq 0} \|\rho(t, \cdot)\|_{L^\infty(\mathbb{R}^2)} \leq C,$$

where C depends only on the initial data. Moreover the log-moment grows at most linearly in time

$$N(t) = \int_{\mathbb{R}^2} \ln(1 + |x|^2) \rho(t, x) dx \leq N(0) + Ct,$$

where again C depends only on the initial data.

We shall also state the existence result for radial initial data that was obtained in [50] and [46] for higher dimensions and the Newtonian potential. Similar methods can be applied in the case $d = 2$ considered here:

Theorem 4.2 (Properties of radial solutions). *Let $\rho_0 \in L^1_{log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$ be nonnegative and radially symmetric.*

- (a) *Then the corresponding unique weak solution of (4.1) remains radially symmetric for all $t > 0$.*
- (b) *If ρ_0 is compactly supported, then the solution remains compactly supported for all $t > 0$.*

(c) If ρ_0 is moreover monotonically decreasing, then the solution remains radially decreasing for all $t > 0$.

In the remainder of this section we carry out the proof of the existence of a bounded global weak solution to (4.1) as stated in Theorem 4.1. We therefore introduce the following regularization of (4.1)

$$\partial_t \rho_\varepsilon = \Delta(\rho_\varepsilon^m + \varepsilon \rho_\varepsilon) - \nabla \cdot (\rho_\varepsilon \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon), \quad (4.4)$$

where $m > 1$ and the regularized logarithmic interaction potential is defined as

$$\mathcal{N}_\varepsilon(x) = -\frac{1}{4\pi} \log(|x|^2 + \varepsilon^2).$$

Moreover we have for the derivatives

$$\nabla \mathcal{N}_\varepsilon = -\frac{1}{2\pi} \frac{x}{|x|^2 + \varepsilon^2}, \quad \Delta \mathcal{N}_\varepsilon = -\frac{1}{\pi} \frac{\varepsilon^2}{(|x|^2 + \varepsilon^2)^2} = -J_\varepsilon$$

satisfying

$$\|J_\varepsilon\|_{L^1(\mathbb{R}^2)} = 1.$$

The regularization in (4.4) was used by Bian and Liu [7], who studied the Keller-Segel equation with nonlinear diffusion and the Newtonian potential for $d \geq 3$, which has been modified accordingly for the logarithmic interaction kernel in $d = 2$. The additional linear diffusion term in (4.4) removes the degeneracy and the regularized logarithmic potential \mathcal{N}_ε possesses a uniformly bounded gradient, such that the local well posedness of (4.4) is a standard result for any $\varepsilon > 0$. We shall note that a slightly different regularization for such nonlinear diffusion Keller-Segel type of equations has been introduced by Sugiyama in [63], which also yields the existence and uniqueness of a global weak solution. The advantage of the regularization in (4.4) resembling the one in [7] is the fact that the regularized problem satisfies a free energy inequality, that in the limit gives exactly (4.3), whereas in [63] the dissipation term could only be retained with a factor of $3/4$.

We point out that in the case $d = 2$ other a priori estimates are available than in higher space dimensions leading to a different proof for global well posedness of the Cauchy problem for (4.4) and the limit $\varepsilon \rightarrow 0$ compared to [7].

4.1.1. Global well posedness of the regularized Cauchy problem. To derive a priori estimates for the regularized problem (4.4) we use the iterative method used by Kowalczyk [48] based on employing test functions that are powers of $\rho_{\varepsilon,k} = (\rho_\varepsilon - k)_+$ for some $k > 0$. When testing (4.4) against $p\rho_{\varepsilon,k}^{p-1}$ for any $p \geq 2$, we obtain:

$$\begin{aligned} & \frac{d}{dt} \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^p dx \\ &= -\frac{4(p-1)}{p} \int_{\mathbb{R}^2} (m\rho_\varepsilon^{m-1} + \varepsilon) |\nabla \rho_{\varepsilon,k}^{\frac{p}{2}}|^2 dx + p \int_{\mathbb{R}^2} (\rho_{\varepsilon,k} + k) (\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon) \cdot \nabla \rho_{\varepsilon,k}^{p-1} dx \\ &\leq -\frac{4(p-1)}{p} m \int_{\mathbb{R}^2} \rho_\varepsilon^{m-1} |\nabla \rho_{\varepsilon,k}^{\frac{p}{2}}|^2 dx + \int_{\mathbb{R}^2} (\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon) \cdot ((p-1)\nabla \rho_{\varepsilon,k}^p + kp\nabla \rho_{\varepsilon,k}^{p-1}) dx \\ &\leq -\frac{4(p-1)}{p} mk^{m-1} \|\nabla \rho_{\varepsilon,k}^{\frac{p}{2}}\|_{L^2}^2 + \int_{\mathbb{R}^2} J_\varepsilon * \rho_\varepsilon ((p-1)\rho_{\varepsilon,k}^p + kp\rho_{\varepsilon,k}^{p-1}) dx \\ &\leq -\frac{4(p-1)}{p} mk^{m-1} \|\nabla \rho_{\varepsilon,k}^{\frac{p}{2}}\|_{L^2}^2 + \int_{\mathbb{R}^2} (J_\varepsilon * \rho_{\varepsilon,k} + k) ((p-1)\rho_{\varepsilon,k}^p + kp\rho_{\varepsilon,k}^{p-1}) dx \\ &\leq -\frac{4(p-1)}{p} mk^{m-1} \|\nabla \rho_{\varepsilon,k}^{\frac{p}{2}}\|_{L^2}^2 + C(p-1) \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^{p+1} dx + Ckp \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^p dx + k^2 p \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^{p-1} dx, \end{aligned} \quad (4.5)$$

where for estimating the integrals involving convolution terms we used the inequality

$$\int f(x)(g * h)(x) dx \leq C\|f\|_{L^p}\|g\|_{L^q}\|h\|_{L^r}, \quad \frac{1}{p} + \frac{1}{q} + \frac{1}{r} = 2, \quad \text{where } p, q, r \geq 1, \quad (4.6)$$

see e.g. Lieb and Loss [49]. Closing the estimate (4.6) would yield a bound for $\rho_{\varepsilon,k}$ in $L^\infty(0, T; L^p(\mathbb{R}^2))$ and thus also for $\rho_\varepsilon \in L^\infty(0, T; L^p(\mathbb{R}^2))$, since

$$\begin{aligned} \int_{\mathbb{R}^2} \rho_\varepsilon^p dx &\leq k^{p-1} \int_{\{\rho_\varepsilon < k\}} \rho_\varepsilon dx + \int_{\{\rho_\varepsilon \geq k\}} (\rho_\varepsilon - k)^p dx + C(p, k) \int_{\{\rho_\varepsilon \geq k\}} k dx \\ &\leq \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^p dx + (k^{p-1} + C(p, k))M. \end{aligned}$$

Kowalczyk proceeded from (4.5) with the assumption corresponding to $\|\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^\infty} \leq C$. Observe that it would be sufficient to prove $\rho_\varepsilon \in L^\infty(0, T; L^p(\mathbb{R}^2))$ for some $p > 2$ implying $\Delta \mathcal{N}_\varepsilon * \rho_\varepsilon \in L^\infty(0, T; L^p(\mathbb{R}^2))$ and hence the uniform boundedness of the gradient term by Sobolev imbedding. Calvez and Carrillo [19] circumvent this assumption and derive the bound by using an equi-integrability property in the inequality (4.6). Hence, in order to being able to follow the ideas of [19] for the regularized problem, we need to derive the corresponding energy inequality for the latter.

Proposition 4.3. *For any finite time $T > 0$ the solution ρ_ε to the Cauchy problem (4.4) supplemented with initial data $\rho_0 \in L^1_{\log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$ satisfies the energy inequality*

$$\mathcal{E}_\varepsilon[\rho_\varepsilon](t) + \int_0^t \mathcal{D}_\varepsilon[\rho_\varepsilon](t) dt \leq \mathcal{E}_\varepsilon[\rho_0] + \varepsilon C(1+t)t, \quad (4.8)$$

for a positive constant $C = C(M, \|\rho_0\|_\infty)$ and $0 \leq t \leq T$, where \mathcal{E}_ε is an approximation of the free energy functional in (4.2):

$$\mathcal{E}_\varepsilon[\rho_\varepsilon] = \int_{\mathbb{R}^2} \left(\frac{\rho_\varepsilon^m}{m-1} - \frac{\rho_\varepsilon}{2} \mathcal{N}_\varepsilon * \rho_\varepsilon \right) dx$$

and \mathcal{D}_ε the corresponding dissipation

$$\mathcal{D}_\varepsilon[\rho_\varepsilon](t) = \int_{\mathbb{R}^2} \rho_\varepsilon |\nabla h_\varepsilon[\rho_\varepsilon]|^2 dx \quad \text{with} \quad h_\varepsilon[\rho_\varepsilon] = \frac{m}{m-1} \nabla \rho_\varepsilon^{m-1} - \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon.$$

In particular, we obtain equi-integrability

$$\lim_{k \rightarrow \infty} \sup_{t \in [0, T]} \int_{\mathbb{R}^2} (\rho_\varepsilon - k)_+ dx = 0.$$

Proof. Testing (4.4) with $\frac{m}{m-1} \rho_\varepsilon^{m-1} - \mathcal{N}_\varepsilon * \rho_\varepsilon$ we obtain

$$\begin{aligned} \frac{d}{dt} \mathcal{E}_\varepsilon(t) + \int_{\mathbb{R}^2} \rho_\varepsilon \left| \frac{m}{m-1} \nabla \rho_\varepsilon^{m-1} - \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon \right|^2 dx + \varepsilon \frac{4}{m} \int_{\mathbb{R}^2} \left| \nabla \rho_\varepsilon^{\frac{m}{2}} \right|^2 dx \\ = \varepsilon \int_{\mathbb{R}^2} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon \cdot \nabla \rho_\varepsilon dx = \varepsilon \int_{\mathbb{R}^2} \rho_\varepsilon (J_\varepsilon * \rho_\varepsilon) dx \leq \varepsilon \|\rho_\varepsilon\|_{L^2(\mathbb{R}^2)}^2, \end{aligned}$$

where we have used (4.7) and the fact that $\|J_\varepsilon\|_{L^1(\mathbb{R}^2)} = 1$. Hence we need to derive an a priori bound for ρ_ε in $L^2(\mathbb{R}^2)$. We use the estimate (4.6) for $p = 2$ and bound $\int_{\mathbb{R}^2} \rho_{\varepsilon,k}^3 dx$ using the Gagliardo-Nirenberg inequality (see for instance [35], [58]) as follows:

$$\begin{aligned} \|\rho_{\varepsilon,k}\|_{L^3(\mathbb{R}^2)}^3 &\leq C \|\nabla \rho_{\varepsilon,k}\|_{L^2(\mathbb{R}^2)}^2 \|\rho_{\varepsilon,k}\|_{L^1(\mathbb{R}^2)} \\ &\leq CM \|\nabla \rho_{\varepsilon,k}\|_{L^2(\mathbb{R}^2)}^2. \end{aligned}$$

Then by (4.6) and interpolation of the L^2 -integral, we have

$$\begin{aligned} \frac{d}{dt} \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^2 dx &\leq -2mk^{m-1} \|\nabla \rho_{\varepsilon,k}\|_{L^2}^2 + C \int_{\mathbb{R}^2} \rho_{\varepsilon,k}^3 dx + 3k^2 \int_{\mathbb{R}^2} \rho_{\varepsilon,k} dx \\ &\leq -(2mk^{m-1} - CM) \|\nabla \rho_{\varepsilon,k}\|_{L^2}^2 + Ck^2 M. \end{aligned}$$

Hence, choosing k large enough and recalling $m > 1$, we can conclude integrating in time that

$$\|\rho_\varepsilon(t, \cdot)\|_{L^2(\mathbb{R}^2)}^2 \leq C(1+t)$$

for some constant $C = C(M, \|\rho_0\|_{L^\infty(\mathbb{R}^2)})$, which implies the stated energy inequality.

In order to obtain a priori bounds and in particular the equi-integrability property, we need to bound the energy functional also from below. The difference to the corresponding energy functional for the original model (4.1) lies only in the regularized interaction kernel. Since clearly for all $x \in \mathbb{R}^2$ we have $\ln(|x|^2 + \varepsilon^2) \geq 2 \ln |x|$, we obtain

$$\begin{aligned} \mathcal{E}_\varepsilon[\rho_\varepsilon] &= \int_{\mathbb{R}^2} \frac{\rho_\varepsilon^m}{m-1} dx + \frac{1}{8\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x) \ln(|x-y|^2 + \varepsilon^2) \rho_\varepsilon(y) dx dy \\ &\geq \int_{\mathbb{R}^2} \frac{\rho_\varepsilon^m}{m-1} dx + \frac{1}{4\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x) \ln |x-y| \rho_\varepsilon(y) dx dy = \mathcal{E}[\rho_\varepsilon] \end{aligned}$$

Following [19] we can estimate further using the logarithmic Hardy-Littlewood-Sobolev inequality

$$\mathcal{E}_\varepsilon[\rho_\varepsilon] \geq \mathcal{E}[\rho_\varepsilon] \geq -\frac{M}{8\pi} C(M) + \int_{\mathbb{R}^2} \Theta(\rho_\varepsilon) dx, \quad (4.9)$$

where $C(M)$ is a constant depending on the mass M and

$$\Theta(\rho) := \frac{\rho^m}{m-1} - \frac{M}{8\pi} \rho \log \rho.$$

Now it is easy to verify there is a constant $\kappa = \kappa(m, M) > 1$ for which

$$\Theta(\rho) \geq 0 \quad \text{for } \rho \geq \kappa,$$

such that

$$\int_{\mathbb{R}^2} \Theta^-(\rho_\varepsilon) dx = \int_{1 \leq \rho_\varepsilon \leq \kappa} \Theta^-(\rho_\varepsilon) dx \leq \frac{M^2}{8\pi} \log \kappa,$$

implying in particular

$$\mathcal{E}_\varepsilon[\rho_\varepsilon] \geq \mathcal{E}[\rho_\varepsilon] \geq -\frac{M}{8\pi} C(M) - \frac{M^2}{8\pi} \ln \kappa =: \mathcal{E}_*. \quad (4.10)$$

We therefore find from (4.8), (4.9) and (4.10) that

$$\int_{\mathbb{R}^2} \Theta^+(\rho_\varepsilon(t)) dx \leq C + \varepsilon C T^2,$$

with $C = C(m, \|\rho_0\|_{L^1(\mathbb{R}^2)}, \|\rho_0\|_{L^\infty(\mathbb{R}^2)})$ being a constant independent of t . Since Θ^+ is superlinear at infinity, we obtain the equi-integrability as in Theorem 5.3 in [19]. \square

The equi-integrability from Proposition 4.3 allows to close the estimate (4.6) analogously to Lemma 3.1 of [19] leading to a bound for ρ_ε in $L^\infty(0, T; L^p(\mathbb{R}^2))$. Moreover, using Moser's iterative methods of Lemma 3.2 in [19] we finally get a bound for ρ_ε in $L^\infty(0, T; L^\infty(\mathbb{R}^2))$. In order to avoid mass loss at infinity typically the boundedness of the second moment of the solution is employed. We here however demonstrate that the bound of the log-moment provides sufficient compactness, having the advantage of less restrictions on the initial data. We therefore denote for the regularization

$$N_\varepsilon(t) = \int_{\mathbb{R}^2} \ln(1 + |x|^2) \rho_\varepsilon(t, x) dx.$$

The following lemma is now obtained following the ideas of [19]:

Lemma 4.4. *The solution ρ_ε to (4.4) for a nonnegative initial data $\rho_0 \in L^1_{log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$ satisfies for any $T > 0$:*

$$\sup_{t \in [0, T]} \|\rho_\varepsilon(t, \cdot)\|_{L^\infty(\mathbb{R}^2)} + \|N_\varepsilon(t)\|_{L^\infty(0, T)} \leq C(1 + T + \varepsilon T^2),$$

where the constant C depends on the initial data.

Proof. Computing formally the evolution of the log-moment in (4.4) in a similar fashion to [20], we find for the test function $\phi(x) = \ln(1 + |x|^2)$ after integrating by parts

$$\begin{aligned} \frac{d}{dt} N_\varepsilon &= \int_{\mathbb{R}^2} \partial_t \rho_\varepsilon \phi dx = - \int_{\mathbb{R}^2} \rho_\varepsilon \nabla h_\varepsilon[\rho_\varepsilon] \cdot \nabla \phi dx + \varepsilon \int_{\mathbb{R}^2} \rho_\varepsilon \Delta \phi dx \\ &\leq \frac{1}{2} \int_{\mathbb{R}^2} \rho_\varepsilon |\nabla \phi|^2 dx + \frac{1}{2} \int_{\mathbb{R}^2} \rho_\varepsilon |\nabla h_\varepsilon[\rho_\varepsilon]|^2 dx + \varepsilon \int_{\mathbb{R}^2} \rho_\varepsilon \Delta \phi dx. \end{aligned}$$

Computing the derivatives of ϕ we see

$$|\nabla \phi| = \left| \frac{2x}{1 + |x|^2} \right| \leq 1, \quad |\Delta \phi| = \frac{4}{(1 + |x|^2)^2} \leq 4.$$

We thus obtain

$$\frac{d}{dt} N_\varepsilon \leq \frac{1}{2} ((1 + 8\varepsilon)M + \mathcal{D}_\varepsilon[\rho_\varepsilon]).$$

Integration in time and making use of the energy - energy dissipation inequality (4.8) and the uniform bound on \mathcal{E}_ε from below in (4.10) gives

$$N_\varepsilon(t) \leq N_\varepsilon(0) + \frac{1}{2}(1 + 8\varepsilon)Mt + \mathcal{E}_\varepsilon(\rho_0) - \mathcal{E}_* + \varepsilon C(1 + t)t \leq C(1 + t + \varepsilon t^2)$$

The argument can easily be made rigorous by using compactly supported approximations of ϕ on \mathbb{R}^2 as test functions, see e.g. also [11]. The proof is concluded by referring to Lemma 3.2 in [19] for the proof of uniform boundedness of ρ_ε . \square

Remark 4.5.

- (i) *The fact that the uniform bound of ρ_ε grows linearly with time originates from the term of order ε in the energy inequality for the regularized equation. Hence the bound on the energy and therefore the modulus of equi-continuity for the regularized problem are depending on time. However, for the limiting equation (4.1) this term vanishes and the energy is decaying for all times, which allows to deduce uniform boundedness of the solution to (4.1) globally in time and space, see also [19, Lemma 5.7].*
- (ii) *The log-moment of ρ_ε grows at most linearly in time. The same statement is true for the limiting function. Hence it is only possible to guarantee confinement of mass for finite times. This property allowing for compactness results will in the following be used to pass to the limit in the regularized problem. Due to the growth of the bound with time it cannot be employed for the long-time behavior. Hence different methods will be required.*

4.1.2. *The limit $\varepsilon \rightarrow 0$.* In order to deduce the global well posedness of the Cauchy problem for (4.1) it remains to carry out the limit $\varepsilon \rightarrow 0$. Knowing that the solution remains uniformly bounded and having the bounds from the energy inequality, we obtain weak convergence properties of the solution. In order to pass to the limit with the nonlinearities and in the entropy inequality, strong convergence results will be required. The following lemma summarizes the uniform bounds we obtain from Proposition 4.3 and Lemma 4.4:

Lemma 4.6. *Let ρ_ε be the solution as in Proposition 4.3, then we obtain the following uniform in ε bounds*

$$\begin{aligned} \|\rho_\varepsilon\|_{L^\infty(0,T;L^1_{log}(\mathbb{R}^2))} + \|\rho_\varepsilon\|_{L^\infty((0,T)\times\mathbb{R}^2)} &\leq C, \\ \|\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^2((0,T)\times\mathbb{R}^2)} + \|\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^\infty((0,T)\times\mathbb{R}^2)} + \sqrt{\varepsilon} \|\nabla \rho_\varepsilon\|_{L^2((0,T)\times\mathbb{R}^2)} &\leq C, \\ \|\partial_t \rho_\varepsilon\|_{L^2(0,T;H^{-1}(\mathbb{R}^2))} + \|\rho_\varepsilon^q\|_{L^2(0,T;H^1(\mathbb{R}^2))} &\leq C \quad \text{for any } q \geq m - \frac{1}{2}, \end{aligned}$$

where C depends on m, q, ρ_0 and T .

Proof. The uniform bounds of the $L^1_{\log}(\mathbb{R}^2)$ - and $L^\infty(\mathbb{R}^2)$ -norms follow from the conservation of mass and Lemma 4.4. The convolution term

$$\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon = -\frac{1}{2\pi} \int_{\mathbb{R}^2} \frac{y-x}{|y-x|^2 + \varepsilon^2} \rho_\varepsilon(t, y) dy$$

can be estimated as follows:

$$2\pi |\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon| \leq \|\rho_\varepsilon\|_{L^\infty(\mathbb{R}^2)} \int_{|x-y| \leq 1} \frac{1}{|x-y|} dy + M \leq C. \quad (4.11)$$

The bound of $\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon$ in $L^2((0, T) \times \mathbb{R}^2)$ follows now easily by using the conservation of mass.

The basic L^2 -estimate corresponding to (4.5) for $p = 2$ and $k = 0$ implies after integration in time

$$\begin{aligned} \frac{1}{2} \int_{\mathbb{R}^2} \rho_\varepsilon^2 dx &\leq \frac{1}{2} \int_{\mathbb{R}^2} \rho_0^2 dx - \varepsilon \int_0^T \int_{\mathbb{R}^2} |\nabla \rho_\varepsilon|^2 dx dt - m \int_0^T \int_{\mathbb{R}^2} \rho_\varepsilon^{m-1} |\nabla \rho_\varepsilon|^2 dx dt \\ &\quad + \int_0^T \int_{\mathbb{R}^2} (\mathcal{J}_\varepsilon * \rho_\varepsilon) \rho_\varepsilon^2 dx dt. \end{aligned}$$

Using the above a priori estimates we can further bound employing the inequality in (4.7)

$$\varepsilon \|\nabla \rho_\varepsilon\|_{L^2((0, T) \times \mathbb{R}^2)}^2 \leq \frac{1}{2} \int_{\mathbb{R}^2} \rho_0^2 dx + C \int_0^T \int_{\mathbb{R}^2} \rho_\varepsilon^3 dx dt \leq C.$$

Since $m > 1$, the conservation of mass and the uniform boundedness of ρ_ε give $\rho_\varepsilon^{m-1/2}$ in $L^2((0, T) \times \mathbb{R}^2)$. For the gradient we now use the bound on the entropy dissipation (4.8)

$$\begin{aligned} \|\nabla \rho_\varepsilon^{m-1/2}\|_{L^2((0, T) \times \mathbb{R}^2)}^2 &\leq 2 \frac{(m-1/2)^2}{m^2} \left(\int_0^T \mathcal{D}_\varepsilon[\rho_\varepsilon] dt + \|\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^2((0, T) \times \mathbb{R}^2)}^2 \right) \\ &\leq C + C \|\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^\infty((0, T) \times \mathbb{R}^2)}^2 MT. \end{aligned} \quad (4.12)$$

The bound for $\nabla \rho^q$ follows easily by rewriting

$$\frac{m - \frac{1}{2}}{q} \nabla \rho_\varepsilon^q = \rho_\varepsilon^{q-m+\frac{1}{2}} \nabla \rho_\varepsilon^{m-\frac{1}{2}}$$

and using the uniform boundedness of ρ_ε .

It thus now remains to derive the estimate for the time derivative. Using the previous estimates we have for any test function $\phi \in L^2(0, T; H^1(\mathbb{R}^2))$,

$$\begin{aligned} \left| \int_0^T \int_{\mathbb{R}^2} \partial_t \rho_\varepsilon \phi dx dt \right| &\leq \int_0^T \int_{\mathbb{R}^2} |\nabla(\rho_\varepsilon^m + \varepsilon \rho_\varepsilon) \cdot \nabla \phi| dx dt + \int_0^T \int_{\mathbb{R}^2} |\rho_\varepsilon (\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon) \cdot \nabla \phi| dx dt \\ &\leq (\|\nabla \rho_\varepsilon^m\|_{L^2((0, T) \times \mathbb{R}^2)} + \varepsilon \|\nabla \rho_\varepsilon\|_{L^2((0, T) \times \mathbb{R}^2)} \\ &\quad + \|\sqrt{\rho_\varepsilon} |\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon|\|_{L^\infty((0, T) \times \mathbb{R}^2)} \sqrt{TM}) \|\nabla \phi\|_{L^2((0, T) \times \mathbb{R}^2)} \\ &\leq C \|\nabla \phi\|_{L^2((0, T) \times \mathbb{R}^2)}. \end{aligned}$$

□

We now use these bounds to derive weak convergence properties. The Dubinskii Lemma (see Lemma 4.22 in the Appendix) can be applied to obtain the strong convergence locally in space, which can be extended to global strong convergence using the boundedness of the log-moment.

Lemma 4.7. *Let ρ_ε be the solution as in Proposition 4.3. Then, up to a subsequence,*

$$\rho_\varepsilon \rightarrow \rho \quad \text{in } L^q((0, T) \times \mathbb{R}^2) \quad \text{for any } 1 \leq q < \infty, \quad (4.13)$$

$$\rho_\varepsilon^p \rightharpoonup \rho^p \quad \text{in } L^2(0, T; H^1(\mathbb{R}^2)) \quad \text{for any } m - \frac{1}{2} \leq p < \infty, \quad (4.14)$$

$$\sqrt{\rho_\varepsilon} \rightarrow \sqrt{\rho} \quad \text{in } L^2((0, T) \times \mathbb{R}^2), \quad (4.15)$$

$$\varepsilon \nabla \rho_\varepsilon \rightarrow 0 \quad \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2) \quad (4.16)$$

Proof. Since $\{\rho_\varepsilon\}_\varepsilon$ are uniformly bounded in $L^q((0, T) \times \mathbb{R}^2)$ for any $1 \leq q \leq \infty$, we obtain from the reflexivity of the Lebesgue spaces for $1 < q < \infty$ the weak convergence

$$\rho_\varepsilon \rightharpoonup \rho \quad \text{in } L^q((0, T) \times \mathbb{R}^2) \quad \text{for any } 1 < q < \infty. \quad (4.17)$$

Moreover due to the uniform bounds from Lemma 4.6

$$\|\partial_t \rho_\varepsilon\|_{L^2(0, T; H^{-1}(\mathbb{R}^2))} + \|\rho_\varepsilon^r\|_{L^2(0, T; H^1(\mathbb{R}^2))} \leq C$$

for any $r \geq m - \frac{1}{2}$, we can apply the Dubinskii Lemma stated in the Appendix to derive

$$\rho_\varepsilon \rightarrow \rho \quad \text{in } L^r((0, T) \times B_R(0)) \quad \text{for any } 2m \leq r < \infty \text{ and any } R > 0.$$

The boundedness of the log-moment $N(t)$ allows to extend the strong convergence to the whole space, since for any $1 \leq q < \infty$ we have

$$\int_0^T \int_{|x| > R} \rho_\varepsilon^q dx dt \leq \|\rho_\varepsilon\|_{L^\infty((0, T) \times \mathbb{R}^2)}^{q-1} \int_0^T \int_{|x| > R} \frac{\ln(1 + |x|^2)}{\ln(1 + R^2)} \rho_\varepsilon dx dt \leq \frac{C(1 + T)}{\ln(1 + R^2)} \rightarrow 0,$$

as $R \rightarrow \infty$. Due to the weak lower semi-continuity of the L^q -norm we can now conclude with (4.17) that also

$$\int_{|x| > R} \rho^q(t, x) dx \leq \liminf_{\varepsilon > 0} \int_{|x| > R} \rho_\varepsilon^q(t, x) dx \rightarrow 0 \quad \text{as } R \rightarrow \infty \quad \text{for all } q \geq 1.$$

Hence we can extend the strong convergence locally in space to strong convergence in \mathbb{R}^2 :

$$\rho_\varepsilon \rightarrow \rho \quad \text{in } L^r((0, T) \times \mathbb{R}^2) \quad \text{for any } 2m \leq r < \infty.$$

Additionally the strong convergence in $L^1((0, T) \times \mathbb{R}^2)$ can be deduced using the bound from the energy as stated in Lemma 4.21 in the Appendix. Interpolation now yields (4.13).

The weak convergence of $\rho_\varepsilon^{m-1/2}$ in $L^2(0, T; H^1(\mathbb{R}^2))$ holds due to its uniform boundedness given by inequality (4.12) and the reflexivity of the latter space, where the limit is identified arguing by the density of spaces. Due to the uniform boundedness of ρ_ε this assertion can be extended to any finite power bigger than $m - 1/2$.

Since moreover $\sqrt{\rho_\varepsilon}$ is uniformly bounded in $L^2((0, T) \times \mathbb{R}^2)$ we have the weak convergence towards $\sqrt{\rho}$ in $L^2((0, T) \times \mathbb{R}^2)$, where again the limit is identified by using the a.e. convergence of ρ_ε from the strong convergence above. To see (4.15) we rewrite

$$\begin{aligned} \|\sqrt{\rho_\varepsilon} - \sqrt{\rho}\|_{L^2((0, T) \times \mathbb{R}^2)}^2 &= \int_0^T \int_{\mathbb{R}^2} (\rho_\varepsilon - 2\sqrt{\rho_\varepsilon} \sqrt{\rho} + \rho) dx dt \\ &= \int_0^T \int_{\mathbb{R}^2} (\rho_\varepsilon - \rho) dx dt - 2 \int_0^T \int_{\mathbb{R}^2} \sqrt{\rho} (\sqrt{\rho_\varepsilon} - \sqrt{\rho}) dx dt. \end{aligned}$$

The first integral vanishes and the second one converges to 0 due to the weak convergence of $\sqrt{\rho_\varepsilon} \rightharpoonup \sqrt{\rho}$ in $L^2((0, T) \times \mathbb{R}^2)$.

Finally the convergence in (4.16) is a direct consequence of the bound $\sqrt{\varepsilon} \|\nabla \rho_\varepsilon\|_{L^2((0, T) \times \mathbb{R}^2)} \leq C$ in Lemma 4.6. \square

These convergence results from Lemma 4.7 are sufficient to obtain the weak convergence of the nonlinearities $\sqrt{\rho_\varepsilon} \nabla h_\varepsilon[\rho_\varepsilon]$ and $\rho_\varepsilon \nabla h_\varepsilon[\rho_\varepsilon]$ in $L^2((0, T) \times \mathbb{R}^2)$, which allow to pass to the limit in the weak formulation and to deduce the weak lower semicontinuity of the entropy dissipation term:

Lemma 4.8. *Let ρ_ε and ρ be as in Lemma 4.7. Then*

$$\sqrt{\rho_\varepsilon} \nabla h_\varepsilon[\rho_\varepsilon] \rightharpoonup \sqrt{\rho} \nabla h[\rho] \quad \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2) \quad (4.18)$$

$$\rho_\varepsilon \nabla h_\varepsilon[\rho_\varepsilon] \rightharpoonup \rho \nabla h[\rho] \quad \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2). \quad (4.19)$$

Proof. Due to (4.14) and (4.15) it remains to verify

$$\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon \rightharpoonup \sqrt{\rho} \nabla \mathcal{N} * \rho \quad \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2).$$

Due to Lemma 4.6, we have the weak convergence of $\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon$ in $L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2)$. In order to identify the limit we consider for a $\phi \in L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2)$:

$$\begin{aligned} & \int_0^T \int_{\mathbb{R}^2} (\sqrt{\rho_\varepsilon} \nabla \mathcal{N}_\varepsilon * \rho_\varepsilon - \sqrt{\rho} \nabla \mathcal{N} * \rho) \cdot \phi \, dx dt \\ &= \int_0^T \int_{\mathbb{R}^2} (\sqrt{\rho_\varepsilon} - \sqrt{\rho}) (\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon) \cdot \phi \, dx dt + \int_0^T \int_{\mathbb{R}^2} \sqrt{\rho} (\nabla (\mathcal{N}_\varepsilon - \mathcal{N}) * \rho_\varepsilon) \cdot \phi \, dx dt \\ & \quad + \int_0^T \int_{\mathbb{R}^2} \sqrt{\rho} \nabla \mathcal{N} * (\rho_\varepsilon - \rho) \cdot \phi \, dx dt \end{aligned} \quad (4.20)$$

The first term converges to zero using (4.15), since by (4.11) it is bounded by

$$\|\sqrt{\rho_\varepsilon} - \sqrt{\rho}\|_{L^2((0, T) \times \mathbb{R}^2)} \|\nabla \mathcal{N}_\varepsilon * \rho_\varepsilon\|_{L^\infty((0, T) \times \mathbb{R}^2)} \|\phi\|_{L^2((0, T) \times \mathbb{R}^2)} \leq C \|\sqrt{\rho_\varepsilon} - \sqrt{\rho}\|_{L^2((0, T) \times \mathbb{R}^2)} \rightarrow 0.$$

For the second term we first use the Cauchy-Schwarz inequality

$$\int_0^T \int_{\mathbb{R}^2} \sqrt{\rho} (\nabla (\mathcal{N}_\varepsilon - \mathcal{N}) * \rho_\varepsilon) \cdot \phi \, dx dt \leq \sqrt{MT} \|\phi\|_{L^2((0, T) \times \mathbb{R}^2)} \|\nabla (\mathcal{N}_\varepsilon - \mathcal{N}) * \rho_\varepsilon\|_{L^\infty((0, T) \times \mathbb{R}^2)}.$$

To see that this convolution term vanishes we bound further

$$\begin{aligned} |\nabla (\mathcal{N}_\varepsilon - \mathcal{N}) * \rho_\varepsilon| &= \left| \int_{\mathbb{R}^2} \left(\frac{x-y}{|x-y|^2 + \varepsilon^2} - \frac{x-y}{|x-y|^2} \right) \rho_\varepsilon(y) dy \right| \\ &\leq \varepsilon^2 \|\rho_\varepsilon\|_{L^\infty(\mathbb{R}^2)} \int_{\mathbb{R}^2} \frac{|x-y|}{(|x-y|^2 + \varepsilon^2)|x-y|^2} dy = \varepsilon C \int_0^\infty \frac{1}{s^2 + 1} ds \leq \varepsilon C \rightarrow 0 \end{aligned}$$

uniformly in x, t , where we substituted $s = |x-y|/\varepsilon$. For the remaining term in (4.20) we proceed changing the order of integration, where we again skip the dependence of ρ_ε and ϕ on t in the following:

$$\begin{aligned} & \int_0^T \int_{\mathbb{R}^2} \sqrt{\rho} (\nabla \mathcal{N} * (\rho_\varepsilon - \rho)) \cdot \phi \, dx dt \\ &= \frac{1}{2\pi} \int_0^T \int_{\mathbb{R}^2} \left(\sqrt{\rho_\varepsilon(y)} - \sqrt{\rho(y)} \right) \left(\sqrt{\rho_\varepsilon(y)} + \sqrt{\rho(y)} \right) \left(\int_{\mathbb{R}^2} \sqrt{\rho(x)} \frac{x-y}{|x-y|^2} \cdot \phi(x) dx \right) dy dt \\ &\leq \frac{1}{2\pi} \|\sqrt{\rho_\varepsilon} - \sqrt{\rho}\|_{L^2((0, T) \times \mathbb{R}^2)} \left\| \left(\sqrt{\rho_\varepsilon(\cdot)} + \sqrt{\rho(\cdot)} \right) \left(\int_{\mathbb{R}^2} \sqrt{\rho(x)} \frac{1}{|x-\cdot|} |\phi(x)| dx \right) \right\|_{L^2((0, T) \times \mathbb{R}^2)} \end{aligned}$$

To prove that this integral vanishes in the limit, due to (4.15) it suffices to show that

$$\int_0^T \int_{\mathbb{R}^2} \left(\left(\sqrt{\rho_\varepsilon(y)} + \sqrt{\rho(y)} \right) \int_{\mathbb{R}^2} \sqrt{\rho(x)} \frac{1}{|x-y|} |\phi(x)| dx \right)^2 dy dt \leq C.$$

We shall therefore split the integral into two parts and consider first

$$\begin{aligned}
& \int_0^T \int_{\mathbb{R}^2} \left(\left(\sqrt{\rho_\varepsilon(y)} + \sqrt{\rho(y)} \right) \int_{|x-y| \leq 1} \sqrt{\rho(x)} \frac{1}{|x-y|} |\phi(x)| dx \right)^2 dy dt \\
& \leq 2 \int_0^T \int_{\mathbb{R}^2} (\rho_\varepsilon(y) + \rho(y)) \left(\int_{|x-y| \leq 1} |\phi|^2(x) \frac{1}{|x-y|} dx \right) \left(\int_{|x-y| \leq 1} \rho(x) \frac{1}{|x-y|} dx \right) dy dt \\
& \leq C \|\rho\|_{L^\infty((0,T) \times \mathbb{R}^2)} (\|\rho\|_{L^\infty((0,T) \times \mathbb{R}^2)} + \|\rho_\varepsilon\|_{L^\infty((0,T) \times \mathbb{R}^2)}) \int_0^T \int_{\mathbb{R}^2} \int_{|x-y| \leq 1} \frac{|\phi|^2(x)}{|x-y|} dy dx dt \\
& \leq C \int_0^T \int_{\mathbb{R}^2} |\phi|^2(x) \left(\int_{|x-y| \leq 1} \frac{1}{|x-y|} dy \right) dx dt \leq C \|\phi\|_{L^2((0,T) \times \mathbb{R}^2)}^2
\end{aligned}$$

It remains to bound the integral for $|x-y| > 1$:

$$\begin{aligned}
& \int_0^T \int_{\mathbb{R}^2} \left(\left(\sqrt{\rho_\varepsilon(y)} + \sqrt{\rho(y)} \right) \int_{|x-y| > 1} \sqrt{\rho(x)} \frac{1}{|x-y|} |\phi(x)| dx \right)^2 dy dt \\
& \leq 2 \int_0^T \|\phi\|_{L^2(\mathbb{R}^2)}^2 \int_{\mathbb{R}^2} (\rho_\varepsilon(y) + \rho(y)) \int_{|x-y| > 1} \rho(x) \frac{1}{|x-y|^2} dx dy dt \\
& \leq 2M \int_0^T \|\phi\|_{L^2(\mathbb{R}^2)}^2 \int_{\mathbb{R}^2} (\rho_\varepsilon(y) + \rho(y)) dy dt = 4M^2 \|\phi\|_{L^2((0,T) \times \mathbb{R}^2)}^2.
\end{aligned}$$

□

Proof of Theorem 4.1. The convergence property of the nonlinearity in (4.19) and the weak convergence of the time derivative due to Lemma 4.6 allow to pass to the limit in the weak formulation of the Cauchy problem for (4.1), where the linear diffusion term vanishes due to (4.16). The uniqueness of the solution is implied from Theorem 1.3 and Corollary 6.1 of [25], where we shall not go further into detail here.

It thus remains to pass to the limit in the energy inequality. Since the energy dissipation is weakly lower semicontinuous due to (4.18), we get

$$\int_0^T \mathcal{D}[\rho](t) dt \leq \liminf_{\varepsilon > 0} \int_0^T \mathcal{D}_\varepsilon[\rho_\varepsilon](t) dt.$$

In order to obtain the energy inequality (4.3) in the limit $\varepsilon \rightarrow 0$ it thus remains to show $\mathcal{E}_\varepsilon[\rho_\varepsilon](t) \rightarrow \mathcal{E}[\rho](t)$ for $t \in [0, T]$. Lemma 4.21 and the uniform bounds on ρ_ε in Lemma 4.6 directly imply the strong convergence of ρ_ε in $L^\infty(0, T; L^m(\mathbb{R}^2))$. It is therefore left to prove the convergence for the convolution term and we rewrite

$$\begin{aligned}
-4\pi \int_{\mathbb{R}^2} (\rho_\varepsilon \mathcal{N}_\varepsilon * \rho_\varepsilon - \rho \mathcal{N} * \rho) dx &= \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x) \rho_\varepsilon(y) \ln \frac{|x-y|^2 + \varepsilon^2}{|x-y|^2} dx dy \\
&+ 2 \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} (\rho_\varepsilon(x)(\rho_\varepsilon(y) - \rho(y)) + \rho(y)(\rho_\varepsilon(x) - \rho(x))) \ln |x-y| dx dy.
\end{aligned}$$

We split the domain of integration and first analyze the case $|x-y| \geq 1$. In this domain

$$\int_{\mathbb{R}^2} \int_{|x-y| \geq 1} \rho_\varepsilon(x) \rho_\varepsilon(y) \ln \frac{|x-y|^2 + \varepsilon^2}{|x-y|^2} dx dy \leq \int_{\mathbb{R}^2} \int_{|x-y| \geq 1} \rho_\varepsilon(x) \rho_\varepsilon(y) \ln(1 + \varepsilon^2) dx dy \leq \varepsilon^2 M^2 \rightarrow 0$$

and using the Cauchy-Schwarz inequality we obtain moreover

$$\begin{aligned}
& \left(\int_{\mathbb{R}^2} \int_{|x-y| \geq 1} \rho_\varepsilon(x) (\rho_\varepsilon(y) - \rho(y)) \ln |x-y| dx dy \right)^2 \\
& \leq \|\rho_\varepsilon - \rho\|_{L^1(\mathbb{R}^2)} \int_{\mathbb{R}^2} |\rho_\varepsilon(y) - \rho(y)| \left| \int_{|x-y| \geq 1} \rho_\varepsilon(x) \ln |x-y| dx \right|^2 dy \\
& \leq 2M \|\rho_\varepsilon - \rho\|_{L^1(\mathbb{R}^2)} \int_{\mathbb{R}^2} \int_{|x-y| \geq 1} (\ln(1+|x|) + \ln(1+|y|)) \rho_\varepsilon(x) (\rho_\varepsilon(y) + \rho(y)) dx dy \\
& \leq 4M^2 (N(t) + N_\varepsilon(t)) \|\rho_\varepsilon - \rho\|_{L^1(\mathbb{R}^2)} \leq C(1+T) \|\rho_\varepsilon - \rho\|_{L^\infty(0,T;L^1(\mathbb{R}^2))} \rightarrow 0
\end{aligned}$$

We now turn to the integration domain $|x-y| < 1$ and estimate

$$\begin{aligned}
\int_{\mathbb{R}^2} \int_{|x-y| < 1} \rho_\varepsilon(x) \rho_\varepsilon(y) \ln \frac{|x-y|^2 + \varepsilon^2}{|x-y|^2} dx dy & \leq \|\rho_\varepsilon\|_{L^\infty(\mathbb{R}^2)} \int_{\mathbb{R}^2} \rho_\varepsilon(y) \int_0^1 r \ln \frac{r^2 + \varepsilon^2}{r^2} dr dy \\
& \leq CM \int_0^1 r \ln \frac{r^2 + \varepsilon^2}{r^2} dr
\end{aligned}$$

Within the domain $\sqrt{\varepsilon} < |x-y| = r < 1$, the integrand is bounded by $\ln(1+\varepsilon)$, which converges to 0 as $\varepsilon \rightarrow 0$. For the integral over the remainder of the domain $0 < |x-y| = r < \sqrt{\varepsilon}$, we perform the substitution $r = \varepsilon s$ and split the integral once more, leading to

$$\begin{aligned}
\int_0^{\sqrt{\varepsilon}} r \ln \frac{r^2 + \varepsilon^2}{r^2} dr & = \varepsilon^2 \int_0^1 s \ln \left(1 + \frac{1}{s^2} \right) ds + \varepsilon^2 \int_1^{1/\sqrt{\varepsilon}} s \ln \left(1 + \frac{1}{s^2} \right) ds \\
& \leq \varepsilon^2 C + \varepsilon C \rightarrow 0.
\end{aligned}$$

On the other hand we have

$$\begin{aligned}
& \int_{\mathbb{R}^2} \int_{|x-y| < 1} \rho_\varepsilon(x) |\rho_\varepsilon(y) - \rho(y)| |\ln |x-y|| dx dy \\
& \leq \|\rho_\varepsilon\|_{L^\infty(\mathbb{R}^2)} \int_{\mathbb{R}^2} |\rho_\varepsilon(y) - \rho(y)| \int_{|x-y| < 1} |\ln |x-y|| dx dy \\
& \leq C \|\rho_\varepsilon - \rho\|_{L^1(0,T;L^1(\mathbb{R}^2))} \rightarrow 0.
\end{aligned}$$

This proves the convergence of the entropy, which together with the weak lower semicontinuity of the entropy-dissipation leads to the desired energy-energy dissipation inequality (4.3) for the limiting solution ρ . \square

4.2. Long-Time Behavior of Solutions. Our main result of Section 2 together with the uniqueness argument for radial stationary solutions to (4.1) of [46] and the characterization of global minimizers in [22] and Corollary 3.10 leads to the following result:

Theorem 4.9. *There exists a unique stationary state ρ_M of (4.1) with mass M and zero center of mass in the sense of Definition 2.1 with the property $\rho_M \in L^1_{\log}(\mathbb{R}^2)$. Moreover, ρ_M is compactly supported, bounded, radially symmetric and non-increasing. Moreover, the unique stationary state is characterized as the unique global minimizer of the free energy functional (4.2) with mass M .*

As a consequence, all stationary states of (4.1) in the sense of Definition 2.1 with mass M are given by translations of the given profile ρ_M :

$$\mathcal{S} = \{ \rho_M(x - x_0) \text{ such that } x_0 \in \mathbb{R}^2 \}.$$

Remark 4.10. *As in [46, Corollary 2.3] we have the following result comparing the support and height for stationary states with different masses based on a scaling argument: Let ρ_1 be the radial solution with unit mass. Then the radial solution with mass M is of the form*

$$\rho_M(x) = M^{\frac{1}{m-1}} \rho_1(M^{-\frac{m-2}{2(m-1)}} x).$$

For two stationary states ρ_{M_1} and ρ_{M_2} with masses $M_1 > M_2$ the following relations hold:

- (a) If $m > 2$, then ρ_{M_1} has a bigger support and a bigger height than ρ_{M_2} .
- (b) If $m = 2$, then all stationary states have the same support.
- (c) If $1 < m < 2$, then ρ_{M_1} has smaller support and bigger height than ρ_{M_2} .

We will study now the long time asymptotics for the global weak solutions ρ of (4.1) that according to the entropy inequality in Theorem 4.1 satisfy

$$\lim_{t \rightarrow \infty} \mathcal{E}[\rho](t) + \int_0^\infty \mathcal{D}[\rho](t) dt \leq \mathcal{E}[\rho_0].$$

Since the entropy is bounded from below, this implies for the entropy dissipation

$$\lim_{t \rightarrow \infty} \int_t^\infty \mathcal{D}[\rho](s) ds = 0.$$

Let us therefore now consider the sequence

$$\rho_k(t, x) = \rho(t + t_k, x) \quad \text{on } (0, T) \times \mathbb{R}^2 \quad \text{for some } t_k \rightarrow \infty,$$

for which we obtain

$$0 = \lim_{k \rightarrow \infty} \int_{t_k}^\infty \mathcal{D}[\rho](t) dt \geq \lim_{k \rightarrow \infty} \int_0^T \mathcal{D}[\rho](t + t_k) dt \geq 0.$$

Thus $\mathcal{D}[\rho_k] \rightarrow 0$ in $L^1(0, T)$, or equivalently

$$\|\sqrt{\rho_k} |\nabla h[\rho_k]|\|_{L^2((0, T) \times \mathbb{R}^2)}^2 \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

The proof of convergence towards the steady state will be based on weak lower semicontinuity of the entropy dissipation. Assume that $\rho_k \rightharpoonup \bar{\rho}$ in $L^\infty(0, T; L^1(\mathbb{R}^2) \cap L^m(\mathbb{R}^2))$, then we have to derive

$$\|\sqrt{\bar{\rho}} |\nabla h[\bar{\rho}]|\|_{L^2((0, T) \times \mathbb{R}^2)} \leq \liminf_{k \rightarrow \infty} \|\sqrt{\rho_k} |\nabla h[\rho_k]|\|_{L^2((0, T) \times \mathbb{R}^2)} = 0.$$

Since the L^2 -norm is weakly lower semicontinuous, it therefore remains to show similarly as in Lemma 4.8

$$\sqrt{\rho_k} \nabla h[\rho_k] \rightharpoonup \sqrt{\bar{\rho}} \nabla h[\bar{\rho}] \quad \text{in } L^2((0, T) \times \mathbb{R}^2).$$

From there it can be deduced that $\bar{\rho}$ is the stationary state ρ_M with $M = \|\rho_0\|_{L^1(\mathbb{R}^2)}$ by the uniqueness theorem 4.9, if we can guarantee that no mass gets lost in the limit.

The main difficulty for passing to the limit in the long-time behavior lies in obtaining sufficient compactness avoiding the loss of mass at infinity. Hence, a crucial part for identifying the limiting solution ρ_M as the stationary state with the same mass is proving the weak convergence in $L^1((0, T) \times \mathbb{R}^2)$. Moreover, if we want to choose the right limiting profile among the stationary states in \mathcal{S} , we need to show the conservation of some symmetry. In fact, it is easy to check that the center of mass should formally be preserved by the evolution due to the antisymmetry of the gradient of the Newtonian potential. However, we lack control of the tail of the solutions since the bound on the logarithmic moment of the density is time dependent. We therefore need to develop uniform in time bounds for larger moments of $\rho(t)$. The main theorem of this section is:

Theorem 4.11. *Let ρ be the weak solution to (4.1) given in Theorem 4.1 with nonnegative initial data $\rho_0 \in L^1((1 + |x|^2)dx) \cap L^\infty(\mathbb{R}^2)$. Then, as $t \rightarrow \infty$, $\rho(\cdot, t)$ converges to the unique stationary state with the same mass and center of mass as the initial data, i.e., to*

$$\rho_M^c := \rho_M(x - x_c) \quad \text{where } x_c = \frac{1}{M} \int_{\mathbb{R}^2} x \rho_0(x) dx,$$

with $M = \|\rho_0\|_{L^1(\mathbb{R}^2)}$, ensured by Theorem 4.9. More precisely, we have

$$\lim_{t \rightarrow \infty} \|\rho(t, \cdot) - \rho_M^c(\cdot)\|_{L^q(\mathbb{R}^2)} \rightarrow 0 \quad \text{for all } 1 \leq q < \infty.$$

Our aim is to show that the second moment of solutions to (4.1) is uniformly bounded in time for all $t \geq 0$. This in turn shows easily that the first moment is preserved in time for all $t \geq 0$, as we will prove below. Recall that by (2.13) we denote by $M_2[f]$ the second moment of $f \in L^1_+(\mathbb{R}^d)$. We first derive rigorously the evolution of the second moment in time:

$$M_2[\rho(t, \cdot)] - M_2[\rho(0, \cdot)] = 4 \int_0^t \int_{\mathbb{R}^2} \rho^m dx dt - \frac{tM^2}{2\pi} \quad (4.21)$$

starting from the regularized system (4.4). Computing the second moment of the regularized problem, we obtain

$$\begin{aligned} \frac{d}{dt} M_2[\rho_\varepsilon] &= 4 \int_{\mathbb{R}^2} (\rho_\varepsilon^m + \varepsilon \rho_\varepsilon) dx - \frac{1}{\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x, t) \rho_\varepsilon(y, t) \frac{x \cdot (x - y)}{|x - y|^2 + \varepsilon^2} dx dy \\ &= 4 \int_{\mathbb{R}^2} (\rho_\varepsilon^m + \varepsilon \rho_\varepsilon) dx - \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x, t) \rho_\varepsilon(y, t) \frac{|x - y|^2}{|x - y|^2 + \varepsilon^2} dx dy. \end{aligned}$$

The strong convergence in (4.13) allows to pass to the limit $\varepsilon \rightarrow 0$ in the first integral. In order to pass to the limit in the convolution term we need to split the domain in three parts as follows. First of all, we have

$$\frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{|x-y|>1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) \frac{|x - y|^2}{|x - y|^2 + \varepsilon^2} dx dy = \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{|x-y|>1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) dx dy - R_1^\varepsilon(t)$$

where

$$R_1^\varepsilon(t) = \frac{\varepsilon^2}{2\pi} \int \int_{|x-y|>1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) \frac{1}{|x - y|^2 + \varepsilon^2} dx dy \leq \varepsilon^2 \frac{M^2}{2\pi} \rightarrow 0$$

as $\varepsilon \rightarrow 0$ uniformly in time. Similarly for $\sqrt{\varepsilon} < |x - y| \leq 1$ we have

$$\frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{\sqrt{\varepsilon} < |x-y| \leq 1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) \frac{|x - y|^2}{|x - y|^2 + \varepsilon^2} dx dy = \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{\sqrt{\varepsilon} < |x-y| \leq 1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) dx dy - R_2^\varepsilon(t),$$

where

$$\begin{aligned} R_2^\varepsilon(t) &= \frac{\varepsilon^2}{2\pi} \int_{\mathbb{R}^2} \int_{\sqrt{\varepsilon} < |x-y| \leq 1} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) \frac{1}{|x - y|^2 + \varepsilon^2} dx dy \\ &\leq \varepsilon^2 C_0 M \int_{\sqrt{\varepsilon} < r \leq 1} \frac{r}{r^2 + \varepsilon^2} dr = \varepsilon^2 \frac{C_0 M}{2} (\ln(1 + \varepsilon^2) - \ln(\varepsilon + \varepsilon^2)) \leq C \varepsilon \rightarrow 0 \end{aligned}$$

as $\varepsilon \rightarrow 0$ uniformly in time, where we let $C_0 = \sup_{\varepsilon>0} \|\rho_\varepsilon\|_{L^\infty}$. Finally for the domain $0 < |x - y| \leq \sqrt{\varepsilon}$ we obtain

$$R_3^\varepsilon(t) = \int_{\mathbb{R}^2} \int_{0 < |x-y| < \sqrt{\varepsilon}} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) \frac{|x - y|^2}{|x - y|^2 + \varepsilon^2} dx dy \leq \frac{C_0 M}{2\pi} |B_{\sqrt{\varepsilon}}| \leq \varepsilon C \rightarrow 0$$

as $\varepsilon \rightarrow 0$ uniformly in time. Thus combining all integrals we obtain

$$\begin{aligned} \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(x, t) \rho_\varepsilon(y, t) \frac{|x - y|^2}{|x - y|^2 + \varepsilon^2} dx dy &= \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{|x-y|>\sqrt{\varepsilon}} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) dx dy - R^\varepsilon \\ &\rightarrow \frac{1}{2\pi} \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \rho_\varepsilon(t, x) \rho_\varepsilon(t, y) dx dy = \frac{M^2}{2\pi}, \end{aligned}$$

where we denoted $R^\varepsilon = R_1^\varepsilon + R_2^\varepsilon - R_3^\varepsilon \rightarrow 0$ as $\varepsilon \rightarrow 0$. The argument can easily be made rigorous by using compactly supported approximations of $|x|^2$ on \mathbb{R}^2 as test functions, see e.g. also [11]. We finally obtain (4.21) by integrating in time.

Now, we want to compare general solutions to (4.1) with its radial solutions. In order to do this we will make use of the concept of mass concentration, which has been recalled in (2.4), and used for instance in [46, 32] for classical applications to Keller-Segel type models.

Following exactly the same proof as in [46], the following two results hold for the solutions of (4.1). The first result says that for two radial solutions, if one is initially “more concentrated”

than the other one, then this property is preserved for all time. The second result compares a general (possibly non-radial) solution $\rho(t, \cdot)$ with another solution $\mu(t, \cdot)$ with initial data $\rho^\#(0, \cdot)$, i.e., the decreasing rearrangement of the initial data for $\rho(t, \cdot)$, and it says that the symmetric rearrangement of $\rho(t, \cdot)$ is always “less concentrated” than the radial solution $\mu(t, \cdot)$. This result generalizes the results from [32] to nonlinear diffusion with totally different proofs. We also refer the interested reader to the survey [69] for a general exposition of the mass concentration comparison results for local nonlinear parabolic equations and to the recent developments obtained in [71], [72] in the context of nonlinear parabolic equations with fractional diffusion.

Proposition 4.12. *Let $m > 1$ and f, g be two radially symmetric solutions to (4.1) with $f(0, \cdot) \prec g(0, \cdot)$. Then we have $f(t, \cdot) \prec g(t, \cdot)$ for all $t > 0$.*

Proposition 4.13. *Let $m > 1$ and ρ be a solution to (4.1), and let μ be a solution to (4.1) with initial condition $\mu(0, \cdot) = \rho^\#(0, \cdot)$. Then we have that $\mu(t, \cdot)$ remains radially symmetric for all $t \geq 0$, and in addition we have*

$$\rho^\#(t, \cdot) \prec \mu(t, \cdot) \quad \text{for all } t \geq 0.$$

Now we are ready to bound the second moment of solutions in the two-dimensional case: we will show that if $\rho(t, \cdot)$ is a solution to (4.1) with $M_2[\rho_0]$ finite, then $M_2[\rho(t)]$ must be uniformly bounded for all time.

Theorem 4.14. *Let $\rho_0 \in L^1((1 + |x|^2)dx) \cap L^\infty(\mathbb{R}^2)$. Let $\rho(t, \cdot)$ be the solution to (4.1) with initial data ρ_0 . Then we have that*

$$M_2[\rho(t)] \leq M_2[\rho_0] + C(\|\rho_0\|_{L^1}) \quad \text{for all } t \geq 0.$$

Proof. Recalling that ρ_M is the unique radially symmetric stationary solution with the same mass as ρ_0 and zero center of mass, we let $\rho_{M,\lambda} := \lambda^2 \rho_M(\lambda x)$ with some parameter $\lambda > 1$. Since $\rho_0 \in L^1(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2)$, we can choose a sufficiently large λ such that $\rho_0^\# \prec \rho_{M,\lambda}$. Note that $\lambda > 1$ also directly yields that $\rho_M \prec \rho_{M,\lambda}$.

Let $\mu(t, \cdot)$ be the solution to (4.1) with initial data $\rho_{M,\lambda}$. Combining Proposition 4.12 and Proposition 4.13, we have that

$$\rho^\#(t, \cdot) \prec \mu(t, \cdot) \quad \text{for all } t \geq 0.$$

It then follows from (2.10) that

$$\int_{\mathbb{R}^2} \rho^m(t, x) dx = \int_{\mathbb{R}^2} [\rho^\#]^m(t, x) dx \leq \int_{\mathbb{R}^2} \mu^m(t, x) dx \quad \text{for all } t \geq 0. \quad (4.22)$$

Now using the computation of the time derivative of $M_2[\rho(t)]$ in (4.21), where $\rho(\cdot, t)$ is a solution to (4.1), we get

$$M_2[\rho(t)] - M_2[\rho_0] = 4 \int_0^t \int_{\mathbb{R}^2} \rho^m(t, x) dx dt - \frac{tM^2}{2\pi}. \quad (4.23)$$

Since $\mu(t, \cdot)$ is also a solution to (4.1), (4.23) also holds when ρ is replaced by μ . Combining this fact with (4.22), we thus have

$$M_2[\rho(t)] - M_2[\rho_0] \leq M_2[\mu(t)] - M_2[\mu(0)] \leq M_2[\mu(t)]. \quad (4.24)$$

Finally, it suffices to show $M_2[\mu(t)]$ is uniformly bounded for all time. Since ρ_M is a stationary solution and we have $\rho_M \prec \rho_{M,\lambda}$, it follows from Proposition 4.12 that $\rho_M \prec \mu(t, \cdot)$ for all $t \geq 0$, hence we have $M_2[\rho_M] \geq M_2[\mu(t)]$ due to Lemma 2.6. Plugging this into (4.24) yields

$$M_2[\rho(t)] \leq M_2[\rho_0] + M_2[\rho_M] \quad \text{for all } t \geq 0,$$

where $M_2[\rho_M]$ is a constant only depending on the mass $M := \|\rho_0\|_{L^1(\mathbb{R}^2)}$, which can be computed as follows: using Remark 4.10, we know the support of ρ_M is given by the ball centered at 0 of radius $R(M) = C_0 M^{\frac{m-2}{2(m-1)}}$ (where C_0 is the radius of the support for the stationary solution with unit mass), hence $M_2[\rho_M] \leq MR(M)^2 \leq C_0^2 M^{\frac{2m-3}{m-1}}$. \square

Remark 4.15. *It is interesting the contrast of our last result showing uniform-in-time bounds for the second moment for $m > 1$ finite, with the results in [30, 31] where the case $m \rightarrow \infty$ limit of the gradient flow is analysed. In the “ $m = \infty$ ” case, the second moment of any solution is actually decreasing in time, leading to the result that all solutions converge towards the global minimizer with some explicit rate. As mentioned in the introduction, a result of this sort for any other potential rather than the attractive logarithmic potential is lacking.*

As already mentioned above, a key ingredient in the proof of Theorem 4.11 is the confinement of mass, which is first now obtained as follows:

Lemma 4.16. *Let ρ be a global weak solution as in Theorem 4.1 with mass M with initial data $\rho_0 \in L^1((1 + |x|^2)dx) \cap L^\infty(\mathbb{R}^2)$ and consider as above the sequence $\{\rho_k\}_{k \in \mathbb{N}} = \{\rho(\cdot + t_k, \cdot)\}_{k \in \mathbb{N}}$ in $(0, T) \times \mathbb{R}^2$. Then there exists a $\bar{\rho} \in L^1((0, T) \times \mathbb{R}^2) \cap L^m((0, T) \times \mathbb{R}^2)$ and a subsequence, that we denote with the same index without loss of generality, such that:*

$$\rho_k(t, x) \rightharpoonup \bar{\rho}(t, x) \quad \text{in } L^1((0, T) \times \mathbb{R}^2) \cap L^m((0, T) \times \mathbb{R}^2)$$

as $k \rightarrow \infty$.

Proof. Due to the entropy being uniformly bounded from below and by the entropy inequality (4.2), we have $\rho_k \in L^\infty((0, T); L^m(\mathbb{R}^2))$. Using Theorem 4.14, we deduce that

$$M_2[\rho_k(t)] \leq M_2[\rho_0] + C(\|\rho_0\|_{L^1(\mathbb{R}^2)}) \quad \text{for all } k \in \mathbb{N} \text{ and } 0 \leq t \leq T. \quad (4.25)$$

Since $\{\rho_k\}_{k \in \mathbb{N}}$ are also uniformly bounded in $L^\infty(0, T; L^m(\mathbb{R}^2))$ we obtain equi-integrability and can therefore apply the Dunford-Pettis theorem (see Theorem 4.20 in Appendix) to obtain the weak convergence in $L^1((0, T) \times \mathbb{R}^2) \cap L^m((0, T) \times \mathbb{R}^2)$. \square

In order to obtain weak lower semicontinuity of the entropy dissipation term, we need additional convergence results. These are derived from the following uniform bounds:

Lemma 4.17. *Let ρ be a global weak solution as in Theorem 4.1 with mass M and consider as above the sequence $\{\rho_k\}_{k \in \mathbb{N}} = \{\rho(\cdot + t_k, \cdot)\}_{k \in \mathbb{N}}$ in $(0, T) \times \mathbb{R}^2$. Then*

$$\begin{aligned} \|\rho_k\|_{L^\infty(0, T; L^1(\mathbb{R}^2))} + \|\rho_k\|_{L^\infty((0, T) \times \mathbb{R}^2)} &\leq C \\ \|\sqrt{\rho_k} \nabla \mathcal{N} * \rho_k\|_{L^2((0, T) \times \mathbb{R}^2)} + \|\nabla \mathcal{N} * \rho_k\|_{L^\infty((0, T) \times \mathbb{R}^2)} &\leq C \\ \|\partial_t \rho_k\|_{L^2(0, T; H^{-1}(\mathbb{R}^2))} + \|\rho_k^q\|_{L^2(0, T; H^1(\mathbb{R}^2))} &\leq C \quad \text{for any } q \geq m - \frac{1}{2}. \end{aligned}$$

Proof. The bounds are obtained from the energy-energy dissipation inequality (4.3) in an analogous way to the ones given in Lemma 4.6 with the only difference concerning the replacement of \mathcal{N}_ε by \mathcal{N} , which however makes no difference in the estimate (4.11). \square

Using these estimates the following convergence properties can be derived in an analogous way to the proof of Lemma 4.7.

Lemma 4.18. *Let the assumptions of Lemma 4.16 hold. Then, up to subsequences that we denote with the same index,*

$$\begin{aligned} \rho_k &\rightarrow \bar{\rho} \quad \text{in } L^q((0, T) \times \mathbb{R}^2) \quad \text{for any } 1 \leq q < \infty, \\ \rho_k^p &\rightharpoonup \bar{\rho}^p \quad \text{in } L^2(0, T; H^1(\mathbb{R}^2)) \quad \text{for any } m - \frac{1}{2} \leq p < \infty, \\ \sqrt{\rho_k} &\rightarrow \sqrt{\bar{\rho}} \quad \text{in } L^2((0, T) \times \mathbb{R}^2). \end{aligned}$$

These convergence results from Lemma 4.18 and Lemma 4.16 are sufficient to obtain the weak convergence of the nonlinearities $\sqrt{\rho_k} \nabla h[\rho_k]$ and $\rho_k \nabla h[\rho_k]$ in $L^2((0, T) \times \mathbb{R}^2)$, which allows to deduce the weak lower semicontinuity of the entropy dissipation term and to pass to the limit in the weak formulation of (4.1) in the same way as in the proof of Lemma 4.8.

Lemma 4.19. *Let ρ_k and $\bar{\rho}$ be as in Lemma 4.18. Then*

$$\begin{aligned}\sqrt{\rho_k} \nabla h[\rho_k] &\rightharpoonup \sqrt{\bar{\rho}} \nabla h[\bar{\rho}] && \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2) \\ \rho_k \nabla h[\rho_k] &\rightharpoonup \bar{\rho} \nabla h[\bar{\rho}] && \text{in } L^2((0, T) \times \mathbb{R}^2; \mathbb{R}^2).\end{aligned}$$

This enables us to close the proof of convergence towards the set of stationary states.

Proof of Theorem 4.11. Let us first notice that $\bar{\rho} \in L^\infty((0, T) \times \mathbb{R}^2)$ due to the first convergence in Lemma (4.18) and the uniform in time bound on the weak solutions in Theorem 4.1. Due to the weak lower semicontinuity of the $L^2((0, T) \times \mathbb{R}^2)$ -norm and the bound from below of the entropy as done in Proposition 4.3 implies that $\mathcal{D}[\rho_k] \rightarrow 0$ in $L^1(0, T)$, and as consequence

$$\|\sqrt{\bar{\rho}} |\nabla h[\bar{\rho}]|\|_{L^2((0, T) \times \mathbb{R}^2)}^2 \leq \liminf_{k \rightarrow \infty} \|\sqrt{\rho_k} |\nabla h[\rho_k]|\|_{L^2((0, T) \times \mathbb{R}^2)}^2 = 0.$$

Thus $\bar{\rho}$ solves

$$\bar{\rho} |\nabla h[\bar{\rho}]|^2 = 0 \quad \text{a.e. in } (0, T) \times \mathbb{R}^2. \quad (4.26)$$

Moreover, due to the convergence properties in Lemmas 4.18 and 4.19 the limiting density $\bar{\rho}$ is a weak distributional solution to (4.1) with test functions is $L^2(0, T; H^1(\mathbb{R}^2))$. Due to (4.26), we get that $\bar{\rho} \nabla h[\bar{\rho}] = 0$ a.e. in $(0, T) \times \mathbb{R}^2$ and thus $\partial_t \bar{\rho} = 0$ in $L^2(0, T; H^{-1}(\mathbb{R}^2))$. This yields that $\bar{\rho}(t, x) \equiv \bar{\rho}(x)$ does not depend on time.

Due to the convergence properties in Lemma 4.18, the uniform bound on the second moment (4.25) together with Lemma 4.21 in the Appendix, we can deduce that $\bar{\rho} \in L^1((1 + |x|^2)dx)$ and that $\rho_k \rightarrow \bar{\rho}$ in $L^\infty(0, T; L^1(\mathbb{R}^2))$. In particular, $\bar{\rho}$ has mass M .

Putting together all the properties of $\bar{\rho}$ just proved together with the fact that $\nabla \bar{\rho}^m \in L^2(\mathbb{R}^2)$ due to Lemma (4.18), we infer that $\bar{\rho}$ corresponds to a steady state of equation (4.1) in the sense of Definition 2.1. The uniqueness up to translation of stationary states in Theorem 4.9 shows that $\bar{\rho}$ is a translation of ρ_M , and thus $\bar{\rho} \in \mathcal{S}$. In fact, we have shown that the limit of all convergent sequences $\{\rho_k\}_{k \in \mathbb{N}}$ must be a translation of ρ_M . This in turn shows that the set of accumulation points of any time diverging sequence belongs to \mathcal{S} .

Finally, in order to identify uniquely the limit, we take advantage of the translational invariance. We first remark that the center of mass of the initial data is preserved for all time due to the anti-symmetry of $\nabla \mathcal{N}$. Due to Proposition 4.14, all time diverging sequences have uniformly bounded second moments, thus since $\bar{\rho}$ is an accumulation point of a sequence ρ_k , by Lemma 4.21 we have

$$\begin{aligned}\left| \int_{\mathbb{R}^2} x \bar{\rho}(x) dx - x_c M \right| &= \left| \int_{\mathbb{R}^2} x (\bar{\rho}(x) - \rho_k(t, x)) dx - \int_{\mathbb{R}^2} x (\rho_k(t, x) - \rho_0(x)) dx \right| \\ &\leq \int_{\mathbb{R}^2} |x| |\bar{\rho}(x) - \rho_k(t, x)| dx \leq M_2 [\|\rho_k(t) - \bar{\rho}\|^{1/2} \|\rho_k(t) - \bar{\rho}\|_{L^1(\mathbb{R}^2)}^{1/2}] \\ &\leq C \|\rho_k(t) - \bar{\rho}\|_{L^\infty(0, T; L^1(\mathbb{R}^2))}^{1/2} \rightarrow 0.\end{aligned}$$

Hence all accumulation points of the sequences have the same center of mass as the initial data. Then, all possible limits reduce to the translation of ρ_M to the initial center of mass as desired. \square

APPENDIX

Theorem 4.20 (Dunford-Pettis Theorem). *Let (X, Σ, μ) be a probability space and \mathcal{F} be a bounded subset of $L^1(\mu)$. Then \mathcal{F} is equi-integrable if and only if \mathcal{F} is a relatively compact subset in $L^1(\mu)$ with the weak topology.*

Lemma 4.21. *Let (f_ε) be a sequence of nonnegative functions uniformly bounded in the space $L^\infty(0, T; L^1_{\log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2))$ with $\|f_\varepsilon\|_{L^1(\mathbb{R}^2)} = \|f\|_{L^1(\mathbb{R}^2)} = M$. Assume moreover that $f_\varepsilon \rightarrow f$ a.e. in $\mathbb{R}^2 \times (0, T)$. Then, $f \in L^\infty(0, T; L^1_{\log}(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2))$ and*

$$f_\varepsilon \rightarrow f \quad \text{in } L^\infty(0, T; L^1(\mathbb{R}^2)).$$

The same result holds by replacing the logarithmic moment by the second moment, i.e., by replacing $L^1_{\log}(\mathbb{R}^2)$ by $L^1((1 + |x|^2)dx)$ everywhere.

Proof. A similar argument was used in the proof of Proposition 2.1 in [38]. First observe that by the Fatou lemma, for any $m > 1$

$$\sup_{(0, T)} \int f^m dx = \sup_{(0, T)} \int \lim_{\varepsilon \rightarrow 0} f_\varepsilon^m dx \leq \liminf_{\varepsilon \rightarrow 0} \sup_{(0, T)} \int f_\varepsilon^m dx \leq C.$$

Let now $L > 1$ and $g_\varepsilon = \min\{f_\varepsilon, L\}$. Then $g_\varepsilon \rightarrow g = \min\{f, L\}$ a.e. Let moreover $R > 1$, then by the dominated convergence, it holds for sufficiently small $\varepsilon > 0$ on the ball $B_R(0)$:

$$\sup_{(0, T)} \int_{B_R(0)} |g_\varepsilon - g| dx \leq \frac{C}{L^{m-1}}.$$

and we obtain

$$\begin{aligned} \sup_{(0, T)} \int_{B_R(0)} |f_\varepsilon - f| dx &\leq \sup_{(0, T)} \int_{B_R(0)} |f_\varepsilon - g_\varepsilon| dx + \sup_{(0, T)} \int_{B_R(0)} |g_\varepsilon - g| dx + \sup_{(0, T)} \int_{B_R(0)} |g - f| dx \\ &\leq \sup_{(0, T)} \int_{\{f_\varepsilon \geq L\} \cap B_R(0)} (f_\varepsilon - L) dx + \frac{1}{L^{m-1}} + \sup_{(0, T)} \int_{\{f \geq L\} \cap B_R(0)} (f - L) dx \\ &\leq \sup_{(0, T)} \int_{B_R(0)} \frac{f_\varepsilon^m}{L^{m-1}} dx + \frac{C}{L^{m-1}} + \sup_{(0, T)} \int_{B_R(0)} \frac{f^m}{L^{m-1}} dx \leq \frac{3C}{L^{m-1}}. \end{aligned}$$

Using additionally the confinement of mass from the bound on the log-moment, we obtain

$$\sup_{(0, T)} \int_{\{|x| > R\}} |f_\varepsilon - f| dx \leq \int_{\mathbb{R}^2} \frac{\ln(1 + |x|^2)}{\ln(1 + R^2)} |f_\varepsilon - f| dx \leq \frac{C}{\ln(1 + R^2)} \rightarrow 0 \quad \text{as } R \rightarrow \infty.$$

Since $L > 1$ is arbitrary and $m > 1$, this shows that $f_\varepsilon \rightarrow f$ strongly in $L^\infty(0, T; L^1(\mathbb{R}^2))$. The proof in case we replace $L^1_{\log}(\mathbb{R}^2)$ by $L^1((1 + |x|^2)dx)$ is done analogously. \square

For the proof of the following Dubinskii Lemma we refer to [24] or Theorem 12.1 in [51]:

Lemma 4.22. *Let $\Omega \subset \mathbb{R}^2$ be bounded with $\partial\Omega \in C^{0,1}$ and let $\{f_\varepsilon\}$, $0 < \varepsilon < 1$, satisfy*

$$\|\partial_t f_\varepsilon\|_{L^1(0, T; (H^s(\Omega))')} + \|f_\varepsilon^p\|_{L^q(0, T; H^1(\Omega))} \leq C,$$

for some $p \geq 1$, $q \geq 1$ and $s \geq 0$. Then $\{f_\varepsilon\}$ is relatively compact in $L^p(0, T; L^r(\Omega))$ for any $r < \infty$ and $l < q$.
